The coefficient of the variable *Production_impact* is -7.2 shows that compared to firms not affected by the Covid-19 pandemic in production activities, firms affected by the pandemic in production activities have a revenue lower than the average of about 7.2%. This is entirely consistent with the fact that firms affected by the pandemic in production activities do not have enough input materials or input materials that have increased in price, leading to decreased revenue.

The coefficient of the variable *Sale_market* -12 shows that firms with a domestic market that has shrunk have a revenue lower than the average of about 12% compared to firms with a domestic market that has not shrunk. This can be explained by the fact that when the domestic market shrinks, the demand for the firm's products decreases, which affects its revenue.

The coefficient of the variable *Digital_orient* indicates the awareness of businesses towards digital technology's impact on digital transformation during the Covid-19 pandemic. Specifically, a coefficient of awareness at level 2 is not statistically significant, indicating no difference in revenue between businesses that had already implemented digital technologies prior to Covid-19 and those that started using digital technologies since the pandemic. However, a coefficient of awareness at level 3 is -7 and statistically significant, showing that businesses that had not applied digital technologies had lower revenue than those that had implemented digital technologies, with an average difference of about 7%. This is consistent with the fact that businesses that had already applied digital technologies had the resources to easily undergo digital transformation, and their revenue still increased even during the pandemic.

3.3. Result of non-parametric regression estimation

Table 4 on the estimation results shows that the average revenue level of businesses is forecasted to decrease by about 17%. The signs of the coefficients of the independent variables in the non-parametric regression model are completely consistent with the results in the parametric regression model. This confirms the reliability of the research results.

Table 4. Results of the non-parametric regression model assessing the impact of factors on competitive capacity

Doanh thu	Observed Estimate	Bootstrap Std. Err.	Percentile 95% conf. Interval

4. Discussion and Conclusion

The consequences of the Covid-19 pandemic have had a serious impact on business operations, serving as a warning to companies to quickly grasp the trend of digital transformation in order to quickly overcome the pandemic. The research results also support the resource-based theory, with companies having strong digital resources, such as a workforce with high digital skills and the ability to bear the costs of digital transformation, having a higher ability to transform digitally than companies with weaker digital resources.

The regression results assessing the impact of factors on competitiveness and statistical analysis show that the Covid-19 pandemic has had a negative impact on the revenue of businesses, with the average revenue of businesses decreasing by 17%. The results also show that businesses with a digital transformation capability of 50% or more have a positive impact on revenue, specifically those with a digital transformation capability

of 50%-75% or above 75% have a corresponding ability to increase revenue by about 8% or 14% compared to businesses with a digital transformation rate below 50%.

From the above results, it can be seen that digital transformation is one of the main directions to help businesses overcome crises and develop sustainably. To help the community of businesses overcome difficulties while quickly maximizing the application of digital technology in business activities, the author proposes the following recommendations:

To the government

The government needs to have policies that support credit packages for the block of businesses to create conditions for them to expand their infrastructure capable of applying high-tech applications in business operations. In addition to the government's support for legal procedures, administrative procedures, replacing traditional paper forms, transparency of rules and regulations on data management can be hoped for significant changes in the digital transformation trend at Vietnamese enterprises in the coming time.

On the enterprises

Businesses should also retrain their workforce before implementing digital transformation to improve the digital expertise of workers to meet the requirements of using and applying digital technology, as well as help them understand the role of digital transformation in the business block. At the same time, businesses also need a system of consulting experts to ensure that the digital transformation process maintains the security of personal and corporate data. Businesses should expand foreign markets or partner with foreign-invested enterprises to enhance their competitiveness. From there, businesses can take significant steps in digital transformation, promoting sustainable development in the current context.

National Economics University, Hanoi, Vietnam

Abstract

The purpose of this research is to answer the questions of what is the enterprise's digital transformation, and what factors affect the digital transformation of enterprises in Vietnam. The research model is tested on survey data using SmartPLS technology. Three factors were verified as having a statistically significant impact on the enterprise's digital transformation, including corporate culture, digital business strategy, and technology infrastructure, whereas three others were not, which include an employee competence in information technology, governance, and competitive pressure. This research is a piece of information on enterprise's digital transformation in Vietnam contributed to the literature and is useful for enterprise management.

Keywords: *Enterprise's digital transformation, employee competence in information technology, success of an enterprise's digital transformation.*

1. Introduction

In recent years, especially after the COVID-19 pandemic, Vietnamese businesses have realized the importance of digital transformation and have applied digital technologies in internal management, input procurement, logistics, production, marketing, sales, and payment. I-Cloud is the most widely used tool in internal management, with 60.6% of enterprises in the survey sample conducted by VCCI in 2020, followed by online conferencing systems, task management systems, and processes, approximately 30% of enterprises. In the banking sector, digital transformation has been implemented starting with IoT applications allowing customers to access and use banking services, connect with other digital ecosystems on the Internet, or provide online banking services via applications installed on mobile phones (Luong Minh Quan et. al., 2020). Digital transformation has brought specific benefits to businesses, consumers, and society. The purpose of this research is to answer the question of what digital transformation is, and what factors affect the success of businesses' digital transformation in Vietnam. Two main contents of the article are a literature review on digital transformation, and an empirical analysis of the factors determining the success of Vietnamese enterprise's digital transformation, then management and policy implications drawn.

2. Literature review

2.1. The concept of digital transformation

Digital transformation has received more and more attention; however, it is hard to find a unified definition of it in literature and in practice. Liu *et al.* (2011) argue that the digital transformation of enterprises is the integration of digital technologies into business processes. Bharadwaj *et al.* (2013) consider digital transformation as an organizational strategy built and implemented by leveraging digital resources to create differentiated value. According to Fitzgerald *et al.* (2013), digital transformation is the use of digital technologies to create major improvements in business. Lucas *et al.* (2013) define digital transformation as fundamentally changing traditional ways of doing business by redefining business capabilities, processes, and relationships. According to Mithas *et al.* (2013), digital transformation is the extent to which an organization participates in an information technology activity. Westerman *et al.* (2014b) define digital transformation as the use of technology to radically improve the operational efficiency or reach of an enterprise. Henriette *et al.* (2015) argue that digital transformation is a business model driven by changes associated with the adoption of digital technology in all aspects of human society. According to Piccinini *et al.* (2015b) digital transformation is characterized by the use of new digital technologies to create great improvements in business. Schuchmann & Seufert (2015) define digital transformation as the reorganization of technology and new business models to more effectively engage digital customers at every touch point in the customer experience lifecycle. According to Chaniias & Hess (2016), digital transformation reflects the pervasiveness of changes caused by digital technologies throughout an organization. Hess *et al.* (2016) refer to digital transformation as the changes that digital technology can bring in a company's business model, resulting in a changed product or organizational structure, or in automation of processes. According to Gobbe (2018) digital transformation is the transformation of an organization's business and activities, processes, capabilities and models to make the most of the change and opportunities of digital technologies, and their increasingly rapid impact on society in a strategic and priority manner.

In general, digital transformation is considered to be the incorporation of digital technology into all areas of an enterprise, fundamentally changing operations and management processes, transferring value to customers and company culture.

Digital transformation reduces costs in production and sales processes because the unified digital-based management helps smooth information flow, eliminating unnecessary clues (Mikalf *et al.*, 2020). Digital transformation increases labor productivity because automation reduces labor intensity (Brynjolfsson, 2017), supports dynamic decision-making based on data (Athey, 2017), and overall improvement due to optimization of organizational restructuring (Li, Li, Guo & Li, 2018). Digital transformation increases the efficiency of company assets. Björkdahl (2020) believes that the digital transformation of companies is focused on improving operational processes, that is, reducing actual costs and increasing work efficiency in key business activities.

However, digital transformation also increases the operating costs of businesses because investment must be made in digital resources such as infrastructure (introducing software and hardware related to digital technologies and their maintaining and updating afterward to enable the digital transformation of business activities); outsourcing certain digital services; establish independent branches to exploit digital business in some cases. However, what we are interested in digital transformation is the net benefits to business operations. The research by Guo and Xu (2021) confirms the U-shaped relationship between digital transformation and the financial performance of profit organizations. When revenue reaches a certain level, it creates a synergy to improve the performance of the firm.

According to Morakanyane, Grace & O'Reilly (2017), the characteristics of digital transformation are the behavioral characteristics exhibited by this phenomenon. The behavior of digital transformation is radical, disruptive, evolutionary, continuous, and complex. Digital transformation drivers are the factors that influence and facilitate the digital transformation process. Digital capabilities and maturity, digital technologies, strategies, business models, and so on are the drivers of digital transformation in organizations. Digital transformation impacts are the effects that business organizations experience as a result of digital transformation. These impacts have been categorized as customer-focused and organization-focused. Customer-focused is the impact on customers and organization-focused is the effect on the organization itself. These impacts can be either positive or negative, but the ultimate impact of digital transformation that organizations want to capitalize on is value creation - for both the organization and the customer. The company's three key transformational areas are customer experience, operational processes, and business models (Morakanyane, Grace & O'Reilly, 2017).

According to the Digital Transformation 2017 Report conducted by Microsoft (Microsoft, 2017), the four dimensions of digital transformation are strategy, people, process, and technology; There is a consensus among senior executives interviewed that customer engagement is the most important aspect of all aspects of digital transformation, and they all agreed that digital transformation has great potential in increasing operational effectiveness.

2.2. Factors affecting digital transformation

A lot of pieces of research have been done to identify the factors that influence the success of digital transformation in organizations. Mhlungu, Chen & Alkema (2019) found four groups of factors affecting the success of digital transformation initiatives in organizations, including customer-centricity, governance, innovation, and input procurement. These authors also pointed out that IT and non-IT managers share a common perception of the factors that influence the overall success of an organization's digital transformation. Nguyen Thi Mai Huong and Bui Thi Sen (2021) identified five factors affecting the intention to implement digital transformation of small and medium-sized enterprises in Hanoi, level of technology use, the business culture, technological infrastructure, financial capacity of the enterprise, purpose, and goal of digital transformation. According to Tungpantong, Nilsook, and Wannapiroon (2022), factors affecting the success of digital transformation in universities include strategy, process,

human product/service, data, and technology. Jovica Stanković and Jelena Z. Stanković (2022) confirmed three groups of factors affecting the application of information technology in e-insurance, the first group is technological factors, and the second group is the e-insurance organizational factors, and the third group is environmental factors. According to Ko, Kovacs and Szabó (2022) digital innovations are strongly influenced by corporate and management commitment, less by strategy. In digital transformation, the role of information technology and services departments is less relevant. Nguyen Thi Kim Anh (2022) has drawn from previous studies factors (and scale) affecting the digital transformation of enterprises, including governance, digital business strategy, ability of employees, corporate culture, technology infrastructure, and pressures on the business.

2.3. Research model

Inheriting previous studies, we propose the research model shown in Figure 1.

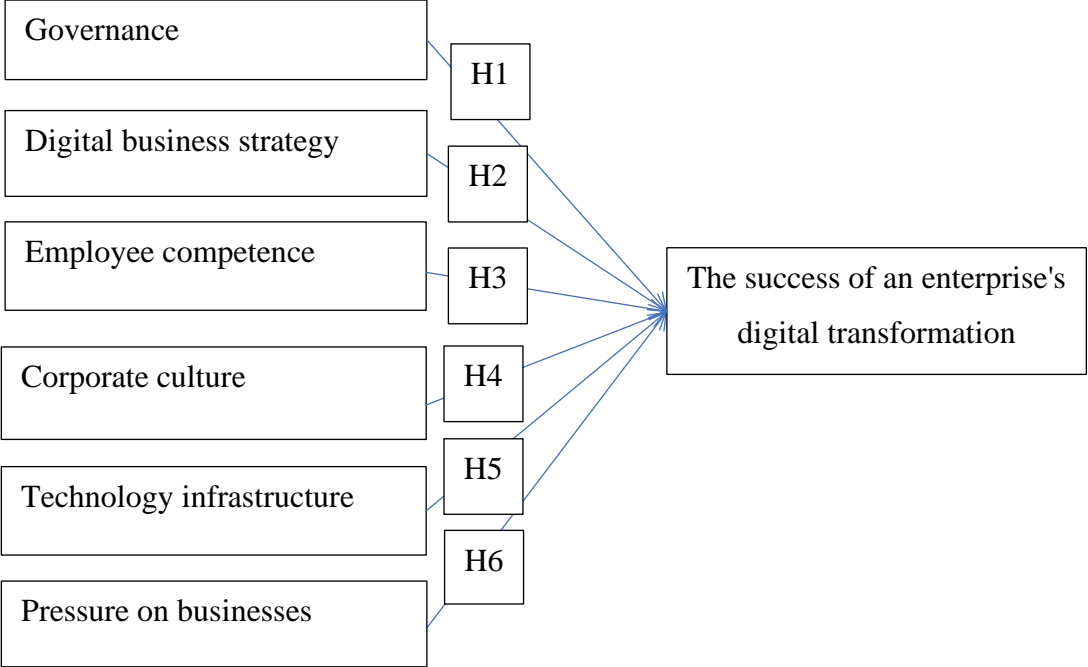

Figure 1. Research model

Governance

Governance is crucial to the success of an organization’s digital transformation. Business leaders are those who are interested in and have a positive attitude towards business's digital transformation, use new digital applications in interacting with employees, constantly learn to develop competence to meet the requirements of digital transformation, and support any digital transformation initiatives and be ready to handle any concern arising from the dark side of the digital transformation process, then the success will be likely. Therefore, we hypothesize that

H1: The enterprise’s governance positively relates to the success of an enterprise's digital transformation.

Digital business strategy

Strategy is the set of decisions made by leaders about the long-term objectives of the organization, and the means, ways, and how to achieve those objectives. If objectives of digital transformation are mentioned in the business strategy, aiming to change the operating model to create new value for customers and businesses, towards optimizing the customer experience on a digital basis, the enterprise has the plan to set up (or has) an electronic office and use the database in decision making, the digital transformation will likely succeed. Thus, we hypothesize that

H2: Digital business strategy positively relates to the success of an enterprise's digital transformation.

Employee competence

Human resources are an important factor in any operation. Digital transformation requires hardware, software, and people to operate. Therefore, enterprises need training programs to create staff specialized in IT, and competent in using IT applications, and employees have a positive attitude toward new technological applications in fulfilling jobs. Thus, we hypothesize that

H3: Employee competence positively relates to the success of an enterprise's digital transformation.

Corporate culture

Digital transformation in organizations is influenced by organizational culture. In the enterprise, if the spirit of learning is always promoted, individuals are active in work, ready to share knowledge and experience with each other, and have cooperative behavior in work, all activities, including with digital conversion will be highly effective. Moreover, it is of great significance to the success of digital transformation if stored information is treated as an enterprise property, and its data is always verified before storing and sharing. Therefore, we hypothesize that

H4: Corporate culture positively relates to the success of an enterprise's digital transformation.

Technology infrastructure

Digital transformation is impossible without a technology infrastructure. A technology infrastructure that allows businesses to use the website to post information and promote their image, employees to use personal electronic devices to do work, use internal interaction systems such as email, OTT tools (Zalo, Viber, Facebook...), and electronic office software to reduce direct communication. The technology infrastructure allows businesses to use iCloud in internal management and create a digital workspace. Thus, we hypothesize that

H5: Technology infrastructure positively relates to the success of an enterprise's digital transformation.

Pressure on businesses

In a fiercely competitive environment, to thrive businesses must attract and "retain" customers, not lose customers to competitors. Digital technologies will help businesses communicate with customers better so that they can provide goods/services that match customer needs, and in many cases, goods/services that businesses provided may be customized. Digital technology allows businesses to optimize business and management processes, create better linkages between departments, use resources more efficiently, and increase transparency and effectiveness in business. management, and innovation in creating products/services for customers. Therefore, we hypothesize that

H6: Pressure on businesses positively relates to the success of an enterprise's digital transformation.

3. Method

Six hypotheses were tested by a quantitative survey on the factors affecting the digital transformation of enterprises in Vietnam, applying structural equation modeling. Details of the research design are provided in the following sections. First, a description of the development of the survey instrument and an introduction of sample subjects. This is followed by identifying measures employed to assess the variables and the scale reliability and validity data are reported. Next, the structural modeling results associated with this survey are presented.

Survey instruments

Based on the extensive literature review, the design a questionnaire was made. The first part of the questionnaire includes questions about a participant's information and the second consists of six multivariate/item scales measuring factors that affect enterprise's digital transformation, using a 5-point Likert scale with increasing agreement from "Not agree at all" to "Completely agree".

Data for this research are collected from a non-probability convenience sample. The online survey was conducted using the Google Form application. The internet address (URL) of the survey was sent to participants via e-mail and uploaded to groups on social networks (Facebook, Zalo, i-Messeges, MS Teams...). The survey was carried out from January to February 2023, and 183 valid responses have been collected, which fulfills the requirement of sample size (Hair *et. al.*, 2014).

The majority of participants are SMEs, accounting for 52%. 135 enterprises own offices registered in Hanoi, 8 in HCM city, and the rest in northern provinces. 20 enterprises operate in the manufacturing industry, accounting for 10.9%, 43 in commerce accounting for 21.5%, 8 in information and communication accounting for 4.4%, 14 in information technology, accounting for 7.7%, 35 in finance and insurance, accounting for 19.1%, and 63 in others, accounting for 34.4%.

Research methods

The research model (Figure 1) was tested by applying structural equation model-based PLS methodology (using SmartPLS software version 4.0.8.9).

Measurement model estimation

Model estimation is the first step in data analysis. An estimation of the internal consistency and the convergent and discriminant validity of the instrument items was conducted to test the measurement model. When reliability measures were above the level recommended of 70 internal consistency is demonstrated (Fornell & Bookstein, 1982; Nunnally & Bernstein, 1994). All reliability measures were above .70 (Table 1), indicating adequate internal consistency. The AVE ranging from 0.783 to 0.834 (Table 1) was above the target of .05 (Chin, 1998; Fornell & Larcker, 1981). The variance shared with the construct and its measures is greater than the error when $AVE > .50$. For all model constructs this level is reached.

When the item loads highly (loading is greater than .50) on their associated factors, convergent validity is demonstrated. If individual reflective measures correlate more than .70 with the construct they intend to measure then they are considered to be reliable.

Table 1. Convergent and discriminant validity of the model constructs

Variable	Outer loading	Variable	Outer loading
Governance		CUL1	0.875
IC = 0.96		CUL2	0.92
AVE = 0.834		CUL3	0.902
GOV1	0.919	CUL4	0.846
GOV2	0.922	CUL5	0.848
GOV3	0.898	CUL6	0.882
GOV4	0.915	Technology infrastructure	
GOV5	0.923	IC = 0.892	
GOV6	0.902	AVE = 0.687	
Digital business strategy		TEC1	0.848
IC = 0.924		TEC2	0.767
AVE = 0.764		TEC3	0.871
STR1	0.86	TEC4	0.794
STR2	0.857	Pressure on businesses	
STR3	0.881	IC = 0.936	
STR4	0.897	AVE = 0.757	
STR5	0.877	PRE1	0.788
Employee competence		PRE2	0.906
IC = 0.889		PRE3	0.88

Variable	Outer loading	Variable	Outer loading
AVE = 0.743		PRE4	0.889
COM1	0.875	PRE5	0.884
COM2	0.863	PRE6	0.868
COM3	0.863	Success of an enterprise's digital transformation	
COM4	0.848	IC = 0.908	
Corporate culture		AVE = 0.783	
IC = 0.942		SUC1	0.887
AVE = 0.773		SUC2	0.896
		SUC3	0.880
		SUC4	0.876

IC = internal consistency (Composite reliability (ρ_a); AVE = average variance extracted

Source: authors extracted from the processed data

Discriminant validity was assessed by comparing the square root of the AVE for each construct with the correlation between the construct with other constructs in the model (Chin, 1998; Fornell & Larcker, 1981). All constructs in the estimated model satisfied the condition of discriminant validity (Table 2).

Table 2. Correlation among construct scores (Discriminant validity - Fornell-Larcker criterion)

	Corporate culture	Employee competence	Governance	Pressure on corporate	Digital business strategy	Success of a enterprise DT	Technology infrastructure
Corporate culture	0.879						
Employees' competence	0.792	0.862					
Governance	0.705	0.661	0.913				
Pressure on corporate	0.708	0.629	0.706	0.87			
Digital business strategy	0.758	0.8	0.776	0.625	0.874		
Success of a enterprise DT	0.742	0.725	0.679	0.654	0.777	0.885	
Technology infrastructure	0.654	0.669	0.752	0.666	0.719	0.739	0.829

Note: The boldface figures in the diagonal represent the square root of the AVE figures. They should be higher than the correlation figures.

Source: authors extracted from the processed data

Table 3. Collinearity statistics - VIF - inner model

Success of an enterprise's digital transformation	
Corporate culture	3.626
Employees' competence	3.695
Governance	3.579
Pressure on corporate	2.553
Digital business strategy	4.219
Technology infrastructure	2.809

Source: authors extracted from the processed data

4. Structural model results

R² for dependent constructs

The results indicate that the structural model explains 70 percent of the variance in the success of an enterprise's digital transformation (Figure 2). The percentage of variance explained for the dependent variable was greater than 10 percent, indicating the satisfactory value of the PLS model (Falk & Miller, 1992).

Structural coefficients

The results of the estimated model show that three of six constructs hypothesized to affect the success of an enterprise's digital transformation were significant, which includes corporate culture (CUL), digital business strategy (STR), and technology infrastructure (TEC), and were supported at $p < .050$. The employees' competence in information technology (COM), governance (GOV), and pressure on enterprises (PRE) were not significant (Table 4).

Table 4. Structure (inner) model results

	Path coefficients	T statistics (O/STDEV)	Sig. level
Effects on the success of a enterprise digital transformation (adjusted R = 0.70)			
Corporate culture	0.222	2.28	**
Employees' competence	0.067	0.722	ns
Governance	-0.082	0.944	ns
Pressure on corporate	0.102	1.404	ns
Digital business strategy	0.341	3.556	****
Technology infrastructure	0.298	3.679	****

**** $p < .001$, ** $p < .050$

ns = not significant

Source: authors extracted from the processed data

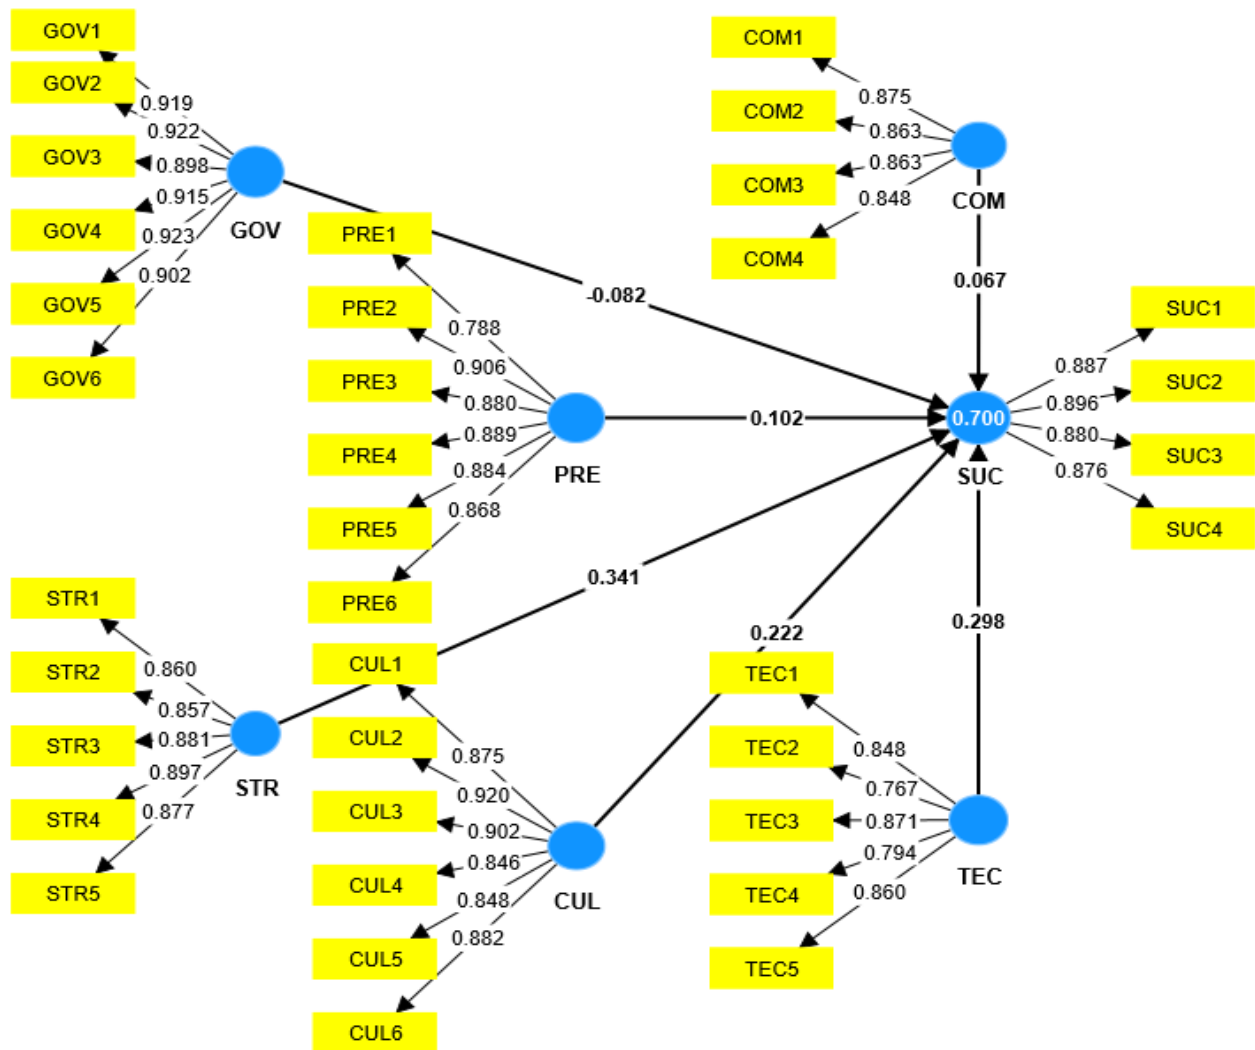

Figure 2. Structural (inner) model results

Effect size (f square)

f square indicates the effect size of independent variables on dependent variables. According to Cohen (1988), $f\text{ square} < 0.02$ indicates an extreme small effect, $0.02 \leq f\text{ square} < 0.15$: shows a small effect; $0.15 \leq f\text{ square} < 0.35$ implies a medium effect; and $f\text{ square} \geq 0.35$: represents a large effect. In the estimated model results demonstrate that corporate culture, digital business strategy, and technology infrastructure have a medium effect, while employee competence, governance, and pressure on the enterprise have a small effect on the success of an enterprise's digital transformation (Table 4).

5. Discussion and conclusion

This research examined factors affecting an enterprise's digital transformation. The model was tested on survey data using SmartPLS technology. Three of the six hypotheses were supported by the data. *Corporate culture*, *digital business strategy*, and *technology infrastructure* significantly affect the enterprise's digital transformation. This is partly in accordance with the findings of Nguyen Thi Mai Huong and Bui Thi Sen (2021),

Wannapiroon (2022), Tungpantong, Nilsook, and Wannapiroon (2022), and Jovica Stanković and Jelena Z. Stanković (2022).

In contrast with previous pieces of research, we found that *employees' competence*, *governance*, and *competitive pressure on corporate* insignificantly influence the enterprise's digital transformation. Mhlungu, Chen & Alkema (2019) found *governance* was one of four groups of factors affecting the success of digital transformation initiatives in organizations; Tungpantong, Nilsook, and Wannapiroon (2022) ascertained *strategy* significant success factor of digital transformation in universities; Jovica Stanković and Jelena Z. Stanković (2022) confirmed *environmental factors* affect the application of information technology in e-insurance.

Practical implications

The research model results imply that corporate culture, digital business strategy, and technology infrastructure influence the success of an enterprise's digital transformation. They are organizational, therefore, to leverage the advantages of digital transformation, enterprises must focus on building a learning organization, sharing knowledge with each other within the organization, and ensuring that stored information is treated as an enterprise property and that its data is always verified before storing and sharing. To ensure the success of the enterprise's digital transformation enterprise's digital business strategy is necessary in place. In addition, enterprises should invest in their own technology infrastructure.

Limitations and directions for further research

No grants were awarded for this research therefore data are collected from a non-probability convenience sample, which may cause bias. Moreover, employee competence, governance, and competitive pressure on corporate theoretically have an impact on the enterprise's digital transformation, therefore further research in the future would examine situations in which they affect the enterprise's digital transformation.

Appendix

Survey questions

Governance

GOV1 = Business leaders are very interested in digital transformation

GOV2 = Leaders have a positive attitude toward business digital transformation

GOV3 = Business leaders use new technology applications in interacting with employees

GOV4 = Business leaders strongly support the application of digitalization of operational and management processes in the enterprise

GOV5 = Leaders are constantly learning to develop their capacity to meet digital transformation requirements

GOV6 = Leaders are ready to address concerns arising from the dark side of digital transformation

Digital business strategy

STR1 = Digital transformation goals are mentioned in the enterprise's business strategy

STR2 = The enterprise determines the plan to establish an electronic office in its strategic plan

STR3 = The enterprise deploys the database system

STR4 = The enterprise's strategy is to change the operating model to create new value for customers

STR5 = The enterprise aims to optimize customer experience on digital platforms

Employee competence

COM1 = Employees have good skills in using information technology applications

COM2 = Enterprise has training programs, equipping employees to use process digitization applications

COM3 = Employees have a positive attitude towards new technology applications in their work

COM4 = Enterprise has employees specialized in the field of information technology

Corporate culture

CUL1 = Each individual in the business is willing to share knowledge and experience with colleagues

CUL2 = The spirit of learning is always appreciated

CUL3 = Each individual is active in the work

CUL4 = The stored information is a common property of the business

CUL5 = Your data is always verified before storing and sharing

CUL6 = The work coordination in the enterprise is very good

Technology infrastructure

TEC1 = Enterprise uses the website to give information and promote its images

TEC2 = Enterprise creates conditions for employees to use personal electronic devices to perform work

TEC3 = Enterprise uses internal interaction systems to reduce face-to-face communication (calling, meeting) such as email, OTT tools (Zalo, Viber, Facebook...), and electronic office software.

TEC4 = Enterprise uses iCloud (which is a computing model using computer technology developed based on the internet) for internal management

TEC5 = Enterprise has created a digital workspace in its working environment

Pressure on enterprise

PRE1 = Enterprise needs digital technologies to better communicate with customers

PRE2 = Enterprise needs optimization of business and management processes

PRE3 = Enterprise needs better alignment between departments

PRE4 = Enterprise needs the more efficient use of resources

PRE5 = Enterprise needs to increase transparency and efficiency in governance

PRE6 = Enterprise needs innovation in creating products/services for customers

Enterprise's digital transformation possibility

SUC1 = Enterprise is fully capable of digital transformation of all business and management processes

SUC2 = Enterprise can completely bring new values and experiences to customers on digital technology platforms

SUC3 = Enterprise is fully capable of successful digital transformation

SUC4 = Enterprise can achieve higher business efficiency after successful digital transformation

FACTORS AFFECTING ORGANIZATIONAL ENGAGEMENT OF EMPLOYEES IN THE CONTEXT OF THE DIGITAL TRANSFORMATION: AN EMPIRICAL EVIDENCE

Nguyen Van Chien
chiennv@tdmu.edu.vn

Thu Dau Mot University, Binh Duong, Vietnam

Abstract

The aims of the study are to evaluate the factors affecting employee engagement in the organization in the context of digital transformation. Using a survey sample of 198 employees living and working in Hanoi, using regression analysis using SPSS software, the research results confirm that the digital transformation does not impact on the employee engagement in the organization. However, the level of promotion, education and training have a positive impact on the engagement of individuals in the organization. In addition, income, and co-worker relationship do not have any impact on engagement through this study. Finally, the study discusses some managerial implications to improve employee engagement in the organization.

Keywords: *Employee, engagement, regressions.*

1. Introduction

Enterprise is considered an important entity in the economy to create jobs, generate income for employees, source of budget revenue and the economic development. The contribution of enterprises to the economy also lies in their ability to contribute to the digital transformation, renew the growth model and especially restore production due to the impacts of the pandemic and macroeconomic instability in recent times. As known, Vietnam in particular and the world in general are heavily affected by the pandemic in the period of 2020 - 2021, which has disrupted supply chains, production, and economies in most of the developing countries that felt into recession. In addition, the world has significantly faced the oil crisis, high oil prices lead to many countries not having enough energy sources for production, including Vietnam since 2022. As a result, the role of enterprises in restoring production and socio-economic development is extremely large.

To create the output of business development, the production function Cobb - Douglas believes that there are three factors that should be considered, respectively: capital, human resources and technology. Human factor is related to employees when they use their health, knowledge and skills to meet production in an enterprise. However, the socio-economic development helps workers with skills and qualifications also have the ability to improve, so workers have many opportunities in finding new jobs to satisfy their own needs. It is likely to affect the cohesion of employees in the enterprise and affect the sustainable development of the enterprise in the long term. However, the country has just experienced

the impact of the pandemic and the economic difficulties in 2022, there have been many impacts on the income, promotion and development of workers and thus have to the employee's commitment to the organization, which is the reason for the formation of this study. At the same time, the rapidly occurring digital transformation context is associated with the transformation of economic activities because the impact of the industrial revolution 4.0 may also have an impact on the cohesion of employees in the organization. .

Previous studies have studied the employee's commitment to the organization and said that income factors, working environment, promotion opportunities and a number of other factors are likely to affect employee commitment to the organization. Cheah et al. (2016) suggested that training and development, organizational equity, and incentives have a significant influence on employees' organizational commitment. Or Ceylan et al (2021) once affirmed the importance of work, relationships at work have a great influence on employee engagement. However, training, promotion and work motivation become important as mentioned in the study by Booth-Kewley et al. (2017).

However, the socio-economic context has changed a lot in Vietnam in recent years, the economy has recovered from the impact of the pandemic, and the industrial revolution 4.0 has been taking place strongly, it has changed the behavior of workers and their level of commitment to the organization. Employees have more opportunities in career development, seeking a favorable working environment. However, there has been no research evaluating the impact of digital transformation on employee engagement, which is the reason for this study.

2. Literature Review

The cohesion of employees is shown by employees feeling excited about the working environment in the enterprise and they always want to accompany and develop together with the enterprise. Employees attached to the business are usually satisfied with the development of the organization and always want to bring their efforts and wisdom to contribute to the development of the organization. It can be said that an enterprise that has the ability to have loyal and engaged employees must be a good and developed enterprise, then the enterprise has the ability to perform well the role of creating and developing business in the market.

Dinh (2020) aimed to develop a research framework to evaluate the factors affecting the commitment to the organization of employees working in foreign direct investment (FDI) enterprises. The study was conducted and sent to 312 employees in FDI enterprises; using quantitative analysis through scale reliability analysis through Cronbach's Alpha, Exploratory Factor Analysis to check internal consistency, reliability, size and value of each variable. Research results show that leadership style has the strongest influence on organizational commitment, followed by job satisfaction and work performance. However, there is no statistical evidence that job satisfaction has an impact on job performance. In addition, the study also showed that leadership style has no indirect impact on job results through job satisfaction, but it indirectly affects organizational commitment through job results.

Research by Cheah et al. (2016) suggests that the biggest challenge that organizations face is changes in the attitudes and working behavior of employees, especially employees of Generation X. Further, Cheah et al. (2016) conducted a study to determine the factors affecting organizational commitment through survey data of 300 Generation X employees and using regression analysis, the authors found that training and development, organizational equity, task orientation, knowledge sharing, compensation and incentives are significantly influencing workers' organizational commitment. This sets out for businesses to always pay attention to training and development, creating a fair competitive environment in the business to create motivation for business development in the volatile business environment nowadays.

Another possibility, Ceylan et al (2021) assessed the influence on commitment and engagement in organizations based on a sample conducted with 205 participants working in an organization. The key findings of the study showed that job commitment is positively affected by organizational trust, the importance of work, relationships at work and negatively affected by self-confidence. Organizational trust and relationship at work have a negative effect on employee's intention to leave. The results of this study can be used by organizations in making strategic decisions about one of their most valuable assets, employees and employee engagement.

Research by Booth-Kewley et al (2017) suggests that organizational commitment is a psychological state that has a strong impact on the likelihood that employees will stay with the organization. In particular, organizational commitment can predict a number of important outcomes, including job performance, morale and perceived readiness, and commitment and engagement in the organization. Booth-Kewley et al (2017) conducted a survey of 1597 people in the United States and performed a quantitative analysis, showing that a number of factors affect the commitment of individuals in the organization, including: motivation, positive perception of training, confidence about promotion, confidence in career ability, social support. In addition, Hirschi & Spurk (2021) suggested that employees often have ambitions to achieve important results and advance at work. Research suggests that ambition to achieve is positively related to organizational commitment, especially when there are many career opportunities in the organization. Overall, employee ambition is generally positive and indirectly beneficial to the assessment of individual job performance, but also poses some risks to organizational retention management.

According to Saha (2016) on a study factors affecting organizational commitment, namely job satisfaction, leadership style and organizational environment. Specifically, a business has the ability to maintain and enhance employee performance and company productivity, the business becomes more efficient. To do that, factors such as working environment, working conditions, salary management, promotion opportunities, job security, relationship with manager, relationship with colleagues and the relationship between managers and employees is the core factor affecting job satisfaction and it is the foundation of employee engagement in the organization. Moreover, the study also confirmed that leadership incentives will encourage employees to commit more to their organizations.

Aspects of the organizational environment that lead to organizational commitment namely training and development, communication satisfaction, performance evaluation, employee empowerment and employee motivation, work. According to the group, trust between employees and managers, employee health and the image of the organization are all important factors affecting employee commitment in the organization.

In the rapidly changing business environment, businesses and the state always face different challenges at work in order to improve labor productivity and at the same time maintain employee engagement in the workplace. Estigoy and Sulasula (2020) conducted a study to evaluate the factors affecting employee commitment in the employee's workplace. The research results emphasize the employee's current working relationship with the manager, colleagues and perception of employee commitment in the workplace and this is a group of factors that affect the employee's commitment to the organization. The study also found that the organization is able to maintain individual beliefs about the working relationship, based on leadership commitment and full awareness from the business, there is an influence on the level of engagement.

Sangperm (2017) researched the level of commitment and factors affecting organizational commitment of employees based on a sample included with 384 employees collected by sampling method. stratification rate. Through survey questionnaires, data is collected and errors are processed, multiple regression analysis is performed and research results are obtained: the level of organizational commitment of employees is affected by the organizational justice, job satisfaction and organizational commitment to job performance. In which, the study confirms that compensation policy, and communication have an influence on organizational commitment at 20.1% with statistical significance at 1%, while variables expressing satisfaction in job (ownership, job description, environment, interpersonal and salary) has an effect on organizational commitment at 35.7% with statistical significance at 1%.

3. Method

3.1. Data source

According to Hoang Trong and Chu Nguyen Mong Ngoc (2008), the sample size must be equal to 5 times the number of variables in the factor analysis. With the number of observed variables of 22, the minimum sample size should be 110. However, this study conducted a survey on a sample size of 202 people. After removing the faulty questionnaires, the number of usable questionnaires was 198. The sample size in this case satisfied the conditions of the quantitative analysis. Data collection time is carried out in February 2023 for employees working at enterprises in the city of Hanoi. The authors conduct the survey by distributing questionnaires to employees working in Hanoi by random method.

3.2. Research Methodology

Based on the research of Sangperm (2017), the study has an extension of the research, the regression equation is as follows:

Regression:

$$Ganket_i = \beta_{0i} + \beta_1 thunhap_i + \beta_2 thangtien_i + \beta_3 congngheso_i + \beta_4 dongnghiep_i + \beta_5 daotao_i + \mu_i$$

Where,

Ganket, which is a variable reflecting individual engagement in the organization, is developed through the research of Saha (2016), Booth-Kewley et al (2017), Hirschi & Spurk (2021);

Thunhap, which is a variable reflecting income, is developed through the study of Saha (2016), Sangperm (2017);

Thangtien, which is an independent variable reflecting the promotion ability of employees, is developed in the study of Saha (2016), Booth-Kewley et al (2017);

Congngheso, which is an independent variable reflecting digital transformation, digital environment and employee engagement, is proposed in this study;

Dongnghiep, which is an independent variable reflecting the relationship between employees and colleagues, is discussed in the study of Saha (2016), Estigoy and Sulasula (2020);

Daotao, which is an independent variable reflecting employees' training and retraining during their work, is mentioned in the study of Saha (2016);

The study used quantitative analysis through multiple regression. In order to do this, the research first conducts the analysis of the scale reliability in order to select a scale with a reliable level and use it in the analysis. Next, study EFA analysis and rotation matrix, then correlation and regression analysis. The results from the regression analysis are used to discuss the results and the managerial implications to increase employee engagement in the organization. In this study, we use the ordinary least squares (OLS) regression analysis.

4. Results

4.1. Descriptive statistics

Table 1. Descriptive statistics

Variable	Obs.	Min	Max	Min	Std.dev
Gender	198	0	1	.55	.499
Age	198	1	4	2.36	.805
Level of qualification	198	1	4	2.46	.778
Job	198	1	4	2.28	1.048
Income	198	1	4	2.35	1.025

Source: The analysis

According to the results of descriptive statistical analysis of the variables, it can be seen that 55% of men and 45% of women participated in this survey. For the age group, the survey sample has the middle age group mainly participating in the survey (corresponding to the mean value of 2.36). Qualifications are mainly college and university graduates, with an average value of 2.46. The average income is quite good, the average value is only 2.35 compared to the largest level of 4.

4.2. VIF Cronbach's alpha test

Table 2. The test of Cronbach's alpha

Variable	Questionnaire	Scale mean if item deleted	Scale variance if item deleted	Corrected item total correlation	Cronbach's Alpha if item deleted	Cronbach's alpha
thunhap1	Employees feel that they are properly compensated	11.09	3.058	.667	.701	0.787
thunhap2	Employees are evaluated fairly	11.19	2.988	.572	.746	
thunhap3	Employees get an annual salary increase	11.11	3.064	.576	.743	
thunhap4	The development of the business helps to improve employee's income	11.18	3.002	.569	.748	
thangtien1	Working environment can encourage promotion	10.97	2.821	.585	.657	0.742
thangtien2	Employees are recognized for their achievements	11.04	2.846	.433	.748	
thangtien3	Employees have the opportunity to develop and be recognized	10.98	2.761	.581	.658	
thangtien4	The company has a clear and transparent evaluation policy	11.11	2.806	.559	.670	
congngheso 1	The company always implements management technology into operations	11.17	3.033	.902	.880	0.927
congngheso 2	Workers are exposed to working technology	11.15	3.236	.771	.925	
congngheso 3	The company intends and implements a number of new technologies to improve productivity	11.18	3.365	.781	.920	

Variable	Questionnaire	Scale mean if item deleted	Scale variance if item deleted	Corrected item total correlation	Cronbach's Alpha if item deleted	Cronbach's alpha
congngheso4	The company regularly reviews the production process and makes appropriate modifications	11.17	3.138	.868	.892	0.633
dongnghiep1	Colleagues are united	11.71	3.132	.294	.639	
dongnghiep2	The company has many activities to connect colleagues	11.37	2.457	.487	.505	
dongnghiep3	Teambuilding has the ability to increase the level of cohesion	11.34	2.702	.442	.543	
dongnghiep4	Always get help from colleagues and share work experiences	11.34	2.572	.431	.550	
daotao1	Training policy always encourages employees to participate	7.29	1.376	.580	.594	0.685
daotao2	Training and retraining are maintained regularly	7.32	1.386	.476	.622	
daotao3	The company encourages employees to train themselves to improve their qualifications and skills	7.39	1.406	.449	.658	
ganket1	Employees want to work long-term at the company	7.23	1.824	.640	.722	0.796
ganket2	Introduce relatives and friends to apply for the company	7.24	1.758	.607	.758	
ganket3	Employees feel satisfied and want to continue working at the company	7.27	1.712	.673	.686	

Source: The analysis

Through Cronbach's alpha analysis, it shows that the variables as thunhap, thangtien, congngheso, dongnghiep, daotao all have coefficients greater than 0.6, thus ensuring the reliability of the scale. For the ganket dependent variable, there is also Cronbach's alpha coefficient greater than 0.6 and therefore it can be confirmed that this variable is reliable. At the same time, the correlation coefficient of the total variable is greater than 0.3, so the reliability level is more assured.

4.3. EFA analysis

Table 3. KMO and Bartlett's test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.832
Bartlett's Test of Sphericity	Approx. Chi-Square	1598.758
	df	171
	Sig.	.000

Source: The analysis

KMO coefficient is achieved when this index must be greater than 0.5, showing that this coefficient reaches 0.832 and is greater than 0.5, so it is guaranteed for EFA analysis. Through Bartlett's test, there is statistical significance, showing that the observed variable has a linear correlation in each factor.

Table 4 presents the total variance extracted, usually above 50% to be satisfied, in this case the cumulative value is 64.699% and greater than 50%, these factors reflect 64.699% of the variation of the variables participating in EFA.

Table 4. Total variance explained

Com.	Eigenvalue			Extraction sums of squared loadings			Roration sums of squared loadings		
	Total	% of variance	Cumu.%	Total	% of variance	Cumu.%	Total	% of variance	Cumu.%
1	5.331	28.056	28.056	5.331	28.056	28.056	3.318	17.462	17.462
2	2.990	15.739	43.795	2.990	15.739	43.795	2.556	13.453	30.916
3	1.511	7.955	51.750	1.511	7.955	51.750	2.495	13.131	44.047
4	1.290	6.789	58.540	1.290	6.789	58.540	1.980	10.422	54.469
5	1.170	6.159	64.699	1.170	6.159	64.699	1.944	10.230	64.699
6	.806	4.241	68.940						

Source: The analysis

4.4. Correlation analysis

Through correlation analysis, the independent variables have low correlation with each other, so there may be no multicollinearity phenomenon and therefore the quality of the regression results becomes more reliable.

Table 5. Correlation analysis

Variable	Items	ganket	thunhap	congngheso	thangtien	dongnghiep	daotao
ganket	Pearson Correlation	1	.363**	.170*	.645**	.285**	.417**

Source: The analysis

Through the results of the regression analysis, it can be confirmed that the ability for promotion and retraining has an impact on the cohesion in the organization. Income, digital technology, and co-worker relationships had no effect on engagement in this case study.

The promotion has a positive effect on engagement, meaning that employees who feel able to advance in their work will increase their engagement in the organization. However, the possibility of promotion only occurs when the enterprise is able to create a clear working environment and has a mechanism to evaluate, encourage and recognize employees at work. When an enterprise has a clear policy to encourage the promotion of employees, they will be motivated to strive for the overall development of the organization and they will become more engaged with the organization. Hirschi & Spurk (2021) suggested that employees often have ambitions to achieve important results and career advancement, and that achievement ambitions are positively related to organizational commitment, especially many career opportunities in the organization.

Training and retraining are considered as a good policy that any business must maintain regularly in order to improve the quality of human resources in the enterprise and to help employees improve production better, have better labor productivity. Through this study, once again, the policy of training and retraining is the right policy capable of improving employee engagement in the organization. The process of training and fostering can take place on the job when the more experienced person trains the less experienced person or the newcomer. Or refresher training can take place through training courses organized by enterprises and through courses that can help businesses improve knowledge, skills and working attitudes. Saha (2016) also asserted that the aspect of organizational environment leads to organizational commitment in particular training and development and can help employees to be satisfied with the working environment in the organization and increase their employee engagement in the organization.

5. Conclusions

The level of employee engagement in the organization shows that the enterprise has maintained a friendly working environment and helps employees feel secure in their work and develop themselves in the organization. Researching on 198 employees working at enterprises in Hanoi, using quantitative analysis, the research results once again confirm that promotion and training have a positive impact on career development and individual engagement in the organization. However, the digital transformation process has not yet affected the cohesion of employees in the organization, similarly, income and co-worker relationships have not had an impact on cohesion. Through the research, there are some managerial implications for enterprises as follows:

Firstly, businesses should continue to maintain an employee evaluation policy based on the encouragement and recognition of employees for the organization's achievements. Policies need to be implemented clearly and transparently and help employees feel confident in the recognition of their achievements and advancement in the business. Secondly, businesses need to improve their training and fostering policies

towards practicality, serving the needs of learning to improve qualifications, training skills and attitudes of employees and thereby helping qualified employees to best meet the assigned tasks in the organization and that is also the foundation to help employees increase their engagement with the organization.

STUDYING CREDIT SCORING MODELLING BY MACHINE LEARNING APPROACHES

Dr. Pham Minh Hoan

hoanpm@neu.edu.vn

Tran Thi Hoa

hoatranthineu2201@gmail.com

School of Information Technology and Digital Economics

National Economics University, Hanoi, Vietnam

Abstract

With the huge growth of financial institution databases, the evaluation of credit issuance decisions begins to improve the decision-making methods of manual judgment and statistical analysis, which greatly improves the reliability and efficiency of credit issuance decisions. Machine learning algorithms, as one of the most important statistical tools, have witnessed increasing importance in supporting credit approval decisions. However, based on the different algorithms of each model and the selection of corresponding parameters in each model, the prediction performances have varied among prediction models. To better evaluate the prediction performance of prevalent models and improve the model construction in the credit approval process, this paper focuses on selection and building a machine learning model that help bank predict the possibility of a customer whether can get the credit card by Python. The experimental models involved in the analysis include Logistic Regression, Random Forest, Logistic Regression, and Support vector machine (SVM). As a result, machine learning is effective for credit card approval prediction, but machine learning cannot completely replace traditional credit approval.

Keywords: *credit scoring modelling, machine learning algorithm, credit issuance decision, credit approval process.*

1. Introduction

Topic: “Studying credit scoring modelling by machine learning approaches” is significant both theoretically and practically. In detail:

- *Theoretically*

Credit risk refers to the risk that a borrower may not repay a loan and that the lender may lose the principal of the loan or the interest associated with it. It is one of the major risks faced by financial institutions. Lenders seek to manage credit risk by designing measurement tools to quantify the risk of default, then by employing mitigation strategies to minimize loan loss in the event a default does occur. One such tool is credit scoring, which is a popular and effective way to control credit risk in the financial industry.

Credit scoring is a statistical analysis performed by lenders and financial institutions to determine the creditworthiness of a person or a small, owner-operated business. It is done

based on credit data such as repayment history, delinquency history, length of credit history, and total debt. For new customers, this data is aggregated from credit agencies and credit groups. A credit scoring model is a mathematical model used to estimate the probability of default - that is, the probability that customers may trigger a credit event such as bankruptcy, obligation default, failure to pay or cross-default events 34. In a credit scoring model, this probability of default is normally presented in the form of a credit score. Credit scoring is a statistical analysis performed by lenders and financial institutions to assess a person's creditworthiness. It is used by lenders to help decide whether to extend or deny credit. A credit score can impact many financial transactions, including mortgages, auto loans, credit cards, and private loans. A good credit score is important if customers plan to borrow for a big-ticket item like a car or a house or sign up for a credit card. Their credit score will determine their down payment, interest rate and ultimately their monthly obligation. It is a measurement of their overall financial health and creditworthiness. Because their credit is a key piece of their financial identity, it's crucial to build good credit early on. Good credit habits include paying their bills on time - which is crucial to growing their scores - and light but regular use of their credit accounts. In summary, having a good credit score can provide many benefits such as access to better loan terms and lower interest rates. It follows them forever and plays a huge role in many major financial situations throughout their life.

Therefore, the topic has systematized the theory of credit risk and machine learning approaches in the financial field. In particular, the topic gives evaluations on the effectiveness of the models, then we choose the most suitable machine learning models for credit scoring. In other words, the topic emphasizes the applicability of machine learning models and evaluates how effective they are for the development of the credit sector.

- *Practically*

In Vietnam, credit is a major activity of commercial banks and interest income accounts for over 50% of total bank income. Therefore, controlling credit risk is one of the main tasks of banks. In this context, research on machine learning approaches in credit risk has practical significance in making policy recommendations for commercial banks in Vietnam.

Besides that, machine learning is a rapidly growing field of artificial intelligence that enables computers to learn and improve their capabilities through data input in the form of real-world interactions and observations. This technology has taken the world by storm and is making significant contributions to many different aspects of modern life. One area where machine learning is having a big impact is in finance and banking. Researchers are working hard to incorporate machine learning techniques into this industry to help detect scams, frauds, and defaulters. Complex decisions are being made every day using pattern recognition algorithms. Machine learning's ability to recognize anomalies and patterns is being heavily used for proper oversight of financial institutions. For example, author KY Tam (1991) showed in his paper that neural networks can be used to assess the performance of banks and help them prepare for bankruptcy. This study helps evaluate the financial condition of a bank and shows the effectiveness of using neural networks over other models. Another example comes from R.H. Davis et al. (1991), who discussed the use of machine

learning algorithms in assessing credit card risk. They performed a comparative analysis of accuracy scores using neural networks and other classifiers. The paper concluded that all the algorithms used had similar accuracy, but time complexity was higher for neural networks. Therefore, our paper wants to find the best machine learning model which can help financial institutions make better decisions.

The research topic focuses on the current state of machine learning model applications in controlling credit risk and evaluating their effectiveness in credit scoring. The goal of this research is to find the most optimal model for this field by analyzing and comparing different machine learning approaches. Based on the results of this research, appropriate policy recommendations can be made to improve and further develop the credit field of commercial banks. This could include suggestions for implementing specific machine learning models or techniques to better control credit risk and accurately assess creditworthiness. By using machine learning to improve credit risk management, banks can make more informed decisions about lending and reduce their exposure to potential losses. This can help strengthen the overall financial stability of the banking industry and support economic growth.

The subject of the study is the set of individual customers along with information about credit history at a foreign bank. Although this audience does not best reflect the situation of banks in Vietnam, the data on the credit history of individual customers in Vietnam is difficult to access and incomplete. So, the authors took a large data set of offshore banks to evaluate the effectiveness of the machine learning approach in credit scoring.

2. Literature review

Credit risk is the risk of loss resulting from a default that does not satisfy its obligations under the terms of the contract, causing the holders of creditor's loss. These responsibilities emerge as a result of loan operations, trade and investment activities, payment and settlement of securities trading on its own and foreign accounts, and so on. (Jílek, 2000) There may be instances where a counterparty fails to respect its obligation and fails to repay completely or partially due principale and interest on schedule.

Most balance-sheet assets and off-balance-sheet transaction series include credit risk (bank acceptances or bank guarantees). Credit risk comprises credit risk default, guarantor risk, and derivative counterparty risk. This risk exists in all sectors of the financial market, although it is particularly prevalent in banks, owing mostly to credit activity and off-balance-sheet transactions such as guarantees. Entering derivative transactions, securities lending, buyback transactions, and negotiation all introduce credit risk. For derivative transactions, an examination of counterparty creditworthiness was performed, and changes were monitored.

Credit appraisal is a critical component in bank credit management decisions. This procedure entails gathering, assessing, and categorizing various credit factors and characteristics in order to make credit choices. Bank loan quality is a crucial factor in competition, survival, and profitability (Abdou & Pointon, 2011).

Credit risk is essential for financial institutions. However, banks and financial organizations need something to evaluate customers' credit situation before digging deeper into the customers' financial insight. This is when they use credit scores, as the first base evaluation.

Credit scoring can be simply defined as the application of statistical models to turn relevant data into numerical metrics that inform credit decisions (Abdou & Pointon, 2011). In the research of Anderson in 2007, it is the commercialization of trust; a natural future evolution of the subjective credit ratings, driven by a demand for objective, rapid, and consistent choices, and enabled by technological improvements.

Credit scoring, which is a credit risk management technique, describes statistical models used to evaluate a person's or a firm's creditworthiness. They have gradually superseded judgmental systems and are now commonly utilized by financial and banking establishments that assess the borrower's credit rating and ability before approving a loan. As a result, credit scoring is at the core of the credit decision-making system. This is especially true in the case of consumer credit (mortgage, credit card, personal loan, etc.). Credit scoring models are also utilized by commercial businesses; however, the results are usually insufficient to make a judgment. For example, they can be completed with the relationship manager's understanding of the firm.

Every financial institution has its credit scoring system. Credit scoring is normally calculated by a system of numerical numbers (differentiate ranges depend on the models each financial institution uses).

These numerical scores are calculated by: Payment history: late payment on credit accounts means a lower credit score, and on time and in full meaning increases in credit score; Public records: bankruptcies, judgments, and collection items might affect the score; The amount owed and loan purpose: level of debt might have an impact on the score, and the purpose of the loan may be linked to creditworthiness; Length of credit history; Credit bureau checks: recent reports might be an impact; New accounts: opening various accounts in a short period might be a bad sign; Social media data: might have an impact on creditworthiness based on personal activity; Mobile data: may provide detailed, defined information and insights into consumer behavior; Utility data: A consistent, organized record of payments may contribute to one's credit score; Commercial data: Working capital loans, financial statements, and operational data might indicate the creditworthiness of a business; Macroeconomic data: A change in the unemployment rate or GDP of a region may affect the credit scores of consumers and businesses in that region. Each financial institution divides its credit scoring system and estimated risk perimeters differently (*Credit Scoring Approaches Guidelines*, 2020).

Khandani et al. (2010) have employed machine learning techniques to build nonlinear non-parametric forecasting approaches to measure consumer credit risk. To identify credit cardholders' defaults, the authors used a credit office data set and commercial bank customer transactions to establish a forecast estimation. Their results indicate cost savings from 6% to 25% of total losses when machine learning forecasting techniques are employed to estimate

the delinquency rates. Besides, their study opens questions of whether aggregated customer credit risk analytics may improve systematic risk estimation.

Yap et al. (2011) used historical payment data from a recreational club and established credit scoring techniques to identify potential club member subscription defaulters. The study results demonstrated that no model outperforms the others among a credit scorecard model, logistic regression, and a decision tree model. Each model generated almost identical accuracy figures.

Zhao et al. (2015) examined a multi-layer perceptron (MLP) neural network's accuracy regarding estimating credit scores efficiently. The authors used a German credit dataset to train and estimate the model's accuracy. Their results indicated an MLP model containing nine hidden units achieved a classification accuracy of 87%, higher than other similar experiments. Their study results proved the trend of MLP models' scoring accuracy by increasing the number of hidden units.

In Addo et al. (2018) the authors examined credit risk scoring by employing various machine and deep learning techniques. The authors used binary classifiers in modeling loan default probability (DP) estimations by incorporating ten key features to test the classifiers' stability by evaluating performance on separate data. Their results indicated that the models such as the logistic regression, random forest, and gradient boosting modeling generated more accurate results than the models based on the neural network approach incorporating various technicalities.

Petropoulos et al. (2019) studied a dataset of loan-level data of the Greek economy of examining credit quality performance and quantification of probability default for an evaluating period of 10 years. The authors used an extended example of classifications of the incorporated machine learning models against traditional methods, such as logistic regression. Their results identified that machine learning models had demonstrated superior performance and forecasting accuracy through the financial credit rating cycle.

Provenzano et al. (2020) introduced machine learning models to compose credit rating and default prediction estimation. They used financial instruments, such as historical balance sheets, bankruptcy statutes, and macroeconomic variables of a Moody's dataset.

Galindo and Tamayo (1997) conducted a comparative analysis, which was done on different statistical and machine learning methods using a mortgage loan dataset to understand their limitations and potential. More than 9,000 models were built using state-of-the-art techniques. The results showed that CART decision-tree models provided the best estimation for default with an average error rate of 8.31%. Neural Networks had an average error rate of 11.00%, while K-Nearest Neighbor had an average error rate of 14.95%. These results outperformed the standard Probit algorithm which had an average error rate of 15.13%.

Kruppa et al (2013) examined a general framework for estimating individual consumer credit risks using machine learning methods such as random forests (RF), k-nearest neighbors (kNN), and bagged k-nearest neighbors (bNN). These methods were applied to a large dataset of complete payment histories for short-term installment credits.

The results showed that regression RF performed better than the optimized logistic regression model, kNN, and bNN on the test data.

Kim, J., & Kang, S. (2018) corporate insolvency can negatively impact the economy. Objective measures and analysis of data can help identify a company's financial risk. With advancements in technology, it has become easier to gather and store data about corporations. The challenge is to mine relevant information from this data to forecast insolvency. Machine learning methods can be used to recognize patterns in the data with high accuracy. He conducted a study on corporate bankruptcy of manufacturing companies in Korea and Poland using experts' opinions and financial measures. The results showed that predictions with accuracy greater than 95% were achievable using machine learning techniques when informative features like experts' assessment were used. However, when using only financial factors to predict bankruptcy, the correlation was not as strong.

Zu Li (2019) discussed the use of machine learning techniques to evaluate the creditworthiness of customers. The study focuses on using the XGBoost algorithm to distinguish between customers who are likely to repay their loans and those who are not. The performance of XGBoost is compared with logistic regression and found to be superior.

Ma and Lv (2018) found that the development of science and technology has led to changes in consumer finance and an increase in financial credit risk. This is particularly true for internet finance, where credit risk can be difficult to control. To address this issue, they introduced an improved machine learning algorithm called MLIA. The MLIA algorithm decomposes the objective function into weighted sums of several basis functions and its performance is compared with logistic regression using three test functions. The study also evaluates the performance of the MLIA algorithm using data from an internet financial company and uses the AUC value as a measure of model performance. The results show that the MLIA algorithm has good predictive ability for financial credit risk and can provide a theoretical reference for future research.

David Mhlanga (2021) used a literature review approach to investigate the impact of machine learning and artificial intelligence on credit risk assessment. It found that these technologies can use alternative data sources to address issues like information asymmetry, adverse selection, and moral hazard. This allows lenders to better assess customers' creditworthiness and enables less privileged people to access credit. The study recommends that financial institutions invest more in these technologies to help financially excluded households obtain credit.

Using machine learning models, the authors observed excellent out-of-sample performance results to reduce the bankruptcy probability or improve credit rating.

3. Method

Machine learning-based systems are growing in popularity in research applications in most disciplines. Considerable decision-making knowledge from data has been acquired in the broad area of machine learning, in which decision-making tree-based ensemble techniques are recognized for supervised classification problems. Thus, classification is an

essential form of data analysis in data mining that formulates models while describing significant data classes (Rastogi and Shim 2000). Accordingly, such models estimate categorical class labels, which can provide users with an enhanced understanding of the data at large Han et al. (2012) resulted in significant advancements in classification accuracy.

Motivated by the preceding literature, we evaluated a large number of machine learning algorithms in our work on credit risk. A set of algorithms that performed well in numerical experiments with real data is explained in more details below:

3.1. Logistic regression

Logistic regression is a type of statistical model that is often used for classification and predictive analytics. It estimates the probability of an event occurring based on a given dataset of independent variables. For example, it can be used to predict whether someone voted or didn't vote in an election based on data such as their age, income, and education level. Since the outcome of logistic regression is a probability, the dependent variable is bounded between 0 and 1. In other words, the predicted probability can never be less than 0 or greater than 1. To make these predictions, logistic regression applies a logit transformation to the odds of the event occurring. The odds are calculated by dividing the probability of success by the probability of failure. The logit transformation involves taking the natural logarithm of these odds. The result of this transformation is known as the log odds or natural logarithm of odds. This value can then be used to make predictions about the likelihood of an event occurring. This is also commonly known as the log odds, or the natural logarithm of odds, and this logistic function is represented by the following formula:

$$\log\left(\frac{p}{1-p}\right) = \beta_0 + \beta_1x_1 + \dots + \beta_qx_q$$

3.2. Decision tree

A decision tree is a type of machine learning algorithm that can be used for both classification and regression tasks. It is a non-parametric supervised learning method that has a hierarchical tree structure with different levels and branches. The tree structure consists of a root node, internal nodes, and leaf nodes. The root node represents the top-level decision based on the most important feature. The internal nodes represent decisions based on other features and the leaf nodes represent the final outcome or class.

Decision tree classifiers have been widely implemented in numerous distinct areas due to their ability to provide detailed decision-making knowledge based on the data set used. The tree flow display is comparable to a progress diagram, with cases being arranged based on their feature values. To create a decision tree, a training set of objects is used. Each object in the training set is associated with one of several classes. If all objects in the training set belong to the same class, then the decision tree for that set consists of a single leaf identified with that class. If not all objects belong to the same class, then a test is applied to divide the training set into subsets based on their outcomes for that test. This test becomes the root of the decision tree and this process is repeated for each subset until all objects in each subset belong to a single class.

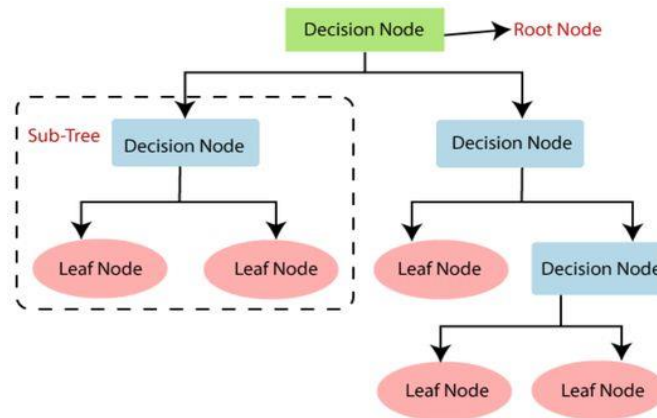

Figure 1. Decision tree

Source: Compiled from the author's team

3.3. Random forest

A random forest is a type of machine learning algorithm that consists of a collection of decision trees. It is an ensemble method that combines the predictions of multiple decision trees to improve the accuracy and robustness of the model. Each tree in the random forest is created using a bootstrap sample drawn from the training data with replacement. This means that some data points may be included multiple times in the sample while others may not be included at all. One-third of this sample is set aside as test data, known as the out-of-bag (oob) sample. To add more diversity to the dataset and reduce correlation among decision trees, feature bagging is used. This involves randomly selecting a subset of features for each tree in the ensemble. This adds randomness to the process and helps prevent overfitting. The way predictions are made depends on whether the problem is a regression or classification task. For regression tasks, the individual decision trees are averaged to make a prediction. For classification tasks, a majority vote is used to determine the predicted class based on which class has been predicted by most trees in the ensemble. The oob sample is then used for cross-validation to finalize the prediction and estimate model performance

Figure 2. Diagram of Random Forest Classifier

Source: Compiled from the author's team

3.4. Support Vector Machine

A Support Vector Machine (SVM) is a supervised machine learning algorithm that can be used for both classification and regression. The objective of the SVM algorithm is to find a hyperplane in an N-dimensional space that distinctly classifies data points. To do this, the algorithm selects the hyperplane that maximizes the margin between the two classes. The margin is defined as the distance between the hyperplane and the closest data points from each class. These closest points are called support vectors. SVMs are powerful tools because they can handle non-linearly separable data by transforming it into a higher dimensional space where it becomes linearly separable. This transformation is done using kernel functions. However, SVMs have some limitations. Their compute and storage requirements increase rapidly with the number of training vectors. The core of an SVM is a quadratic programming problem (QP), separating support vectors from the rest of the training data.

3.5. Adaboost

Freund and Schapire (1995) developed AdaBoost is a powerful classification algorithm. It is a meta-algorithm, meaning that it can be used in conjunction with many other types of learning algorithms to improve their performance. The basic idea behind AdaBoost is to combine the output of several weak learners into a weighted sum to create a final boosted classifier. AdaBoost is adaptive in the sense that it adjusts subsequent weak learners to better classify instances that were misclassified by previous classifiers. This means that the algorithm focuses on harder-to-classify examples as it progresses. In some cases, this can make AdaBoost less susceptible to overfitting than other learning algorithms. While AdaBoost is typically used with weak base learners such as decision stumps (one-level decision trees), it has been shown that it can also effectively combine strong base learners such as deep decision trees. This can produce an even more accurate model. One of the strengths of AdaBoost is its versatility. Every learning algorithm has its strengths and weaknesses and tends to suit some problem types better than others. AdaBoost can be used with many different types of base learners and has many different parameters and configurations that can be adjusted to achieve optimal performance on a given dataset.

AdaBoost is a specific technique for training a boosted classifier. A boosted classifier is a type of classifier that combines the output of several simpler classifiers (known as weak learners) into a weighted sum to create a final, more powerful classifier. AdaBoost is one way to train such a classifier following the form:

$$F_T(x) = \sum_{t=1}^T f_t(x)$$

where each $f(x)$ is a weak learner that takes an object x as input and returns a value indicating the class of the object.

3.6. XGBoost

XGBoost is a powerful machine learning algorithm that is an implementation of gradient-boosting decision trees. It has been widely used by data scientists and researchers

to improve the performance of their machine learning models. XGBoost can help you understand your data better and make more informed decisions based on it. XGBoost is a machine learning algorithm that is designed to be fast and easy to use. It delivers high performance on large datasets and does not require extensive parameter tuning or optimization. This means that you can start using XGBoost right away without any additional configuration.

XGBoost is a widely used implementation of gradient boosting that has several features that make it attractive to users. One of these features is regularization, which helps prevent overfitting by adding L1/L2 penalties on the weights and biases of each tree in the model. This means that the model is less likely to memorize the training data and instead focuses on finding patterns that generalize well to new data.

Another feature of XGBoost is its ability to handle sparse data sets efficiently using the weighted quantile sketch algorithm. This algorithm allows XGBoost to deal with non-zero entries in the feature matrix while retaining the same computational complexity as other algorithms like stochastic gradient descent. This makes it a good choice for datasets with many missing or zero values.

XGBoost also has a block structure for parallel learning, which makes it easy to scale up on multicore machines or clusters. This means that you can train your models faster by taking advantage of multiple processors or nodes. Additionally, XGBoost uses cache awareness to reduce memory usage when training models with large datasets. This helps prevent your computer from running out of memory during training.

Finally, XGBoost offers out-of-core computing capabilities using disk-based data structures instead of in-memory ones during the computation phase. This means that you can train models on datasets that are too large to fit into memory by storing some of the data on disk and loading it into memory as needed.

3.7. LightGBM

LightGBM is a gradient boosting framework that uses decision trees to increase the efficiency of the model and reduce memory usage. It employs two novel techniques called Gradient-based One Side Sampling (GOSS) and Exclusive Feature Bundling (EFB) to overcome the limitations of the histogram-based algorithm used in most GBDT frameworks.

GOSS is a technique that focuses on data instances with larger gradients, which are under-trained instances that contribute more to information gain. Instead of uniformly random sampling, GOSS keeps these instances with large gradients and randomly drops those with small gradients to retain the accuracy of information gain estimation. This approach can lead to more accurate gain estimation than uniformly random sampling, especially when the value of information gain has a large range.

EFB is another technique used by LightGBM that takes advantage of the sparsity of high-dimensional data. In a sparse feature space, many features are mutually exclusive, meaning they never take nonzero values simultaneously. EFB bundles these exclusive

features into a single feature called an Exclusive Feature Bundle. This nearly lossless approach reduces the number of features and improves efficiency.

Together, these two techniques make LightGBM an efficient and powerful GBDT framework that offers several advantages over other implementations.

4. Results

In this section a comparative analysis will be made between the supervised learning models based on the performance metric discussed above. The results will be discussed in using PCA using train test split (pure test set).

4.1. Using pure test set

In this case as we have discussed above the performance metrics will be measured after the train test split where SMOTE has been applied on only on the training set keeping the test set pure.

Table 1. Model prediction results

Details	PCA						
	LR	Decision tree	Random forest	SVM	Adaboost	XGboost	LightGBM
Precision	1	0.9988	0.9965	0.5977	0.9997	0.9996	0.9997
Recall	0.9996	0.9984	0.9999	0.5544	0.9995	0.9994	0.9996
F1 Score	0.9998	0.9986	0.9982	0.5693	0.9996	0.9995	0.9996
AUC Score	1	0.8728	0.9969	0	0.9988	0.9999	0.9998
Accuracy	0.9996	0.9973	0.9965	0.5541	0.9992	0.999	0.9993

Source: Compiled from the author's team

The train test split helps to understand the generalizability of the model and measures the adaptability of the model on new data. In this regard, we see that the tree-based models followed by the logistic regression model produces the best accuracy.

4.2. ROC Curve Analysis

Below we have shown a comparative analysis of all the models using the ROC curves.

(a) ROC Curves for Logistic Regression using PCA

(b) ROC Curves for Decision Tree using PCA

(c) ROC Curves for Random Forest using PCA

(d) ROC Curves for AdaBoost using PCA

(e) ROC Curves for XGboost using PCA

(f) ROC Curves for LightGBM using PCA

Source: Compiled from the author's team

4.3. Confusion Matrix Analysis

There is a need to look at the confusion matrix to assess a classification model's quality of classification. For an ideal confusion matrix, we expect to get values only on the leading/principal diagonal, since they represent correct classification; values off-diagonal are those that were misclassified. Hence, the figures below illustrate the confusion matrix for each of our ensemble classifiers.

(a) Confusion Matrix for Logistic Regression using PCA

(b) Confusion Matrix for Decision Tree using PCA

(c) Confusion Matrix for Random Forest using PCA

(d) Confusion Matrix for SVM using PCA

(e) Confusion Matrix for AdaBoost using PCA

(f) Confusion Matrix for XGboost using PCA

(g) Confusion Matrix for LightGBM using PCA

Source: Compiled from the author's team

The figures above show that most of the values lie along the principal diagonal for all the ensemble classifiers, and the more values we record on the principal diagonal, the more evidence we have of correct classification.

According to the graph, it can be seen that the number of correct bad debt predictions of Logistic Regression and SVM model is the highest. Logistic Regression's number of correct non-performing loan predictions is also the highest. The number of false bad debt predictions of Logistic Regression and SVM is the lowest. Random Forest's number of false predictions is the lowest. Overall, the Logistic Regression model is the most optimal machine learning model.

5. Discussion and Conclusion

5.1. Recommendations for Vietnamese Commercial Banks

First, machine learning is an effective tool for assessing a customer's credit score. Therefore, banks need to promote development and update the latest technology trends to perfect their operational apparatus and improve operational efficiency.

Second, however, machine learning is only a supporting tool, but has not really replaced traditional methods because its accuracy is still not completely absolute. Therefore, banks should not overuse machine learning, instead they should combine machine learning with traditional ways to ensure accuracy and efficiency.

Third, banks need to properly and fully understand customer information because this is a valuable resource that helps banks create highly accurate machine learning models and make credit decisions. correct use for each customer.

5.2. Conclusion

The topic has used secondary data sources provided from a foreign bank and Python to evaluate the model and find the most suitable model for this dataset, to test the effectiveness of machine learning in credit card approval prediction.

The results show that machine learning is effective for credit card approval prediction, but it is not the best choice in all cases. Compared with traditional methods, machine learning can only handle low-complexity jobs and those with automation processes. Therefore, machine learning cannot completely replace traditional credit approval. However, the application of machine learning for credit card approval prediction will become an important premise to develop the financial technology industry in the future in Vietnam.

Abstract

This article aims to examine the influence of individual factors of the UTAUT model combined with the Top Management Support on the behavior of applying Blockchain technology in Logistics enterprises in Vietnam. The study was conducted throughout Vietnam, with a special focus on enterprises located in major cities and provinces of Vietnam such as Hanoi, Ho Chi Minh, Da Nang, Hai Phong, and Quang Ninh. The SEM model was used to test the hypothesis. Based on 508 observations, the research results show that all personal factors (Performance Expectancy, Effort Expectancy, Social Influence, and Facilitating Conditions) and Top Management Support have a positive effect on the behavior of adopting Blockchain technology in Logistics enterprises. In addition, the study also shows that demographic factors including Age and Experience influence the behavior of applying Blockchain technology in businesses.

Keywords: *Vietnam Logistics, Top Management Support, Blockchain adoption, UTAUT*

1. Introduction

Logistics was invented and applied for the first time not in commercial activities but in the military field. In the beginning, Logistics was merely considered a new business method, bringing high efficiency to businesses (Nguyen Thi Thuy Hong, 2023). Along with the development process, Logistics has been specialized and developed into a service industry that plays a very important role in international trade. Therefore, the development of Logistics activities in countries in general and enterprises in particular is an inevitable

trend of the world. Currently, Logistics is being pushed to develop very strongly with the emergence of new technology and digital transformation.

In Vietnam, Logistics plays a substantial part as a pioneering service industry with high added value, as a foundation for trade development, and as a means of improving the economy's competitiveness. This creates a requirement for businesses that need to stay active in a world where the most important thing right now is to accelerate the digital transformation process. Cao Cam Linh, Strategic Director of Viettel Post Joint Stock Corporation, pointed out in the study on "Digital transformation in the Logistics service industry in Vietnam" that the process of implementing technology during the digital transformation period brings many benefits such as eliminating operating costs, attracting more customers, resulting in faster and more accurate decision-making, thus enhancing operational efficiency and business competitiveness (2020). Among the technologies used in the digital transformation era, Blockchain has gained a lot of attention because of the positive attributes it offers to Logistics.

Blockchain technology today is applied to many segments of the supply chain, although not necessarily to the same extent. However, to maximize the benefits and utility of Blockchain, Logistics companies need a variety of detection methods, including multiple sensors, in almost every segment. This requires coordination and cooperation between many players in a typical post-discrete ecosystem. So, the question here is what variables will contribute to the successful application of Blockchain technology for Logistics businesses. Consequently, the authors decided to investigate the topic "*Investigating influential factors of Blockchain integration in the Logistics industry: a case study of Vietnam*".

2. Literature review and hypothesis development

2.1. Literature review

2.1.1. Blockchain Technology

In 1991, Stuart Haber and W. Scott Stornetta released their research on cryptographically safe chains of blocks, which is when the concept of Blockchain technology first emerged. When the Bitcoin white paper was released in 2008 under the alias Satoshi Nakamoto, Blockchain technology became significant. In the scientific literature, there is still no consensus on the exact definition of Blockchain because there exist different scientific directions, such as economics, computer science and law, conflict, and simultaneous terms used in the actual application of the technology.

Blockchain can be defined as a distributed ledger technology that can securely and permanently record transactions between parties. By "sharing" the database between multiple parties, the original Blockchain eliminates the verification of trusted transactions from the middleman (such as transactions through a bank) and records it. By facilitating migration from a centralized point to a distributed system, Blockchain efficiently releases data that was previously kept in secure data stores.

Businesses and consumers are becoming more concerned about social and environmental sustainability (Groening et al., 2018). Through decentralized and immutable

data, trustworthy data, transparency, traceability, smart contracts, and incentives, Blockchain helps to solve several elements of sustainability (Nandi et al., 2020a). Blockchain benefits recovery tactics for the transport chain, particularly through cooperation, agility, speed, and visibility (Hewa et al., 2020; Lohmer et al., 2020).

2.1.2. Logistics Activities

In the world, the term Logistics has been used since the 90s of the 19th century, Logistics is defined as transportation activities serving the military during the war (Simpson and Weiner, 1989; Luttwak, 1971). Over time, Logistics emerged in the business field, defined as a process of gathering materials, manufacturing, and delivering products to the right destinations in the right quantities. Rushton et al. (2009) argue that Logistics is concerned with the efficient movement of goods from the source of production through the place of production to the point of consumption while ensuring cost-effectiveness and quality of service for the customer.

Although there are many different Logistics concepts, they share some common characteristics. First, Logistics is a structured, strict, and ongoing process. Second, Logistics is a series of continuous activities from planning, managing, implementing, and checking the flow of goods, information, capital, etc. throughout the process from input to output of products. Third, Logistics is the process of planning and controlling the flow and storage of goods and services from the point of origin to customer satisfaction. Lastly, Logistics encompasses all raw materials, fuel, resources, and inputs required to produce a product or service (Nguyen Thi Thuy Hong, 2023).

Logistics plays an essential part in economic growth and globalization in Vietnam, accounting for 20.9% of the country's GDP at a scale of 20-22 billion USD per year (GSO). According to Cao Cam Linh (2020), Logistics, as a key service industry with high added value, is the foundation for goods trade, contributing to the economy's competitiveness. With the explosion of digital technology and Industry 4.0, the Logistics industry has many game-changing opportunities to contribute more to the economy if digital transformation is accelerated.

2.1.3. Technology Adoption

The Unified Theory of Acceptance and Use of Technology (UTAUT) was developed by Venkatesh et al. (2003) to explain user intention and behavior toward IT. The UTAUT model is developed based on the following models: Theory of Reasoned Action (TRA) by Fishbein and Ajzen (1975, 1980), Theory of Planned Behavior (TPB) by Ajzen (1985, 1991), Technology Acceptance Model (TAM) by Davis et al. (1989, 1993), TPB and TAM integration model by Taylor and Todd (1995), theoretical model Innovation Diffusion Theory (IDT) of Rogers (1995), Motivational Mode (MM) of Davis et al. (1992), model of computer usage (Model of PC) Utilization (MPCU) by Thompson et al. (1991), and Social Cognitive Theory (SCT) by Compeau and Higgins (1995). TRA, TPB, and TAM have the most influence on UTAUT.

UTAUT identified determinants such as Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI), Facilitating Conditions (FC), and regulatory factors such as Gender, Age, Experience, and Voluntariness of Use. Where PE is defined as the ease with which the system is used; EE is defined as the degree to which an individual believes that using new systems will help him or her to be productive at work; SI refers to the degree to which an individual perceives the importance of being influenced by the beliefs of those around him that the individual should use the new system; FC is defined as the degree to which an individual has confidence that the technical infrastructure of the organization is qualified to support the system (Venkatesh et al., 2003).

UTAUT provides a useful tool for managers to assess the success of new technology introductions and helps them understand the factors that influence the acceptance or rejection of new technology. On that basis, they actively design interventions (including training, marketing, etc) aimed at users, especially those who are afraid of change.

2.2. Hypothesis development

To explore the factors affecting the application of Blockchain technology in Logistics enterprises in Vietnam, the authors built a model based on the UTAUT model of Venkatesh et al. (2003), adding the Top Management Support variable (Figure 1 below). According to Hofstede's Six Dimensions of Culture, Vietnamese culture has a high score in the Power distance dimension, showing that top management significantly influences business activities (Hofstede-insight, 2023). Based on the original UTAUT model combined with the additional variable will help the authors build a general model to assess the factors affecting the behavior of applying Blockchain technology and ensure its relevance to the research context of Vietnam.

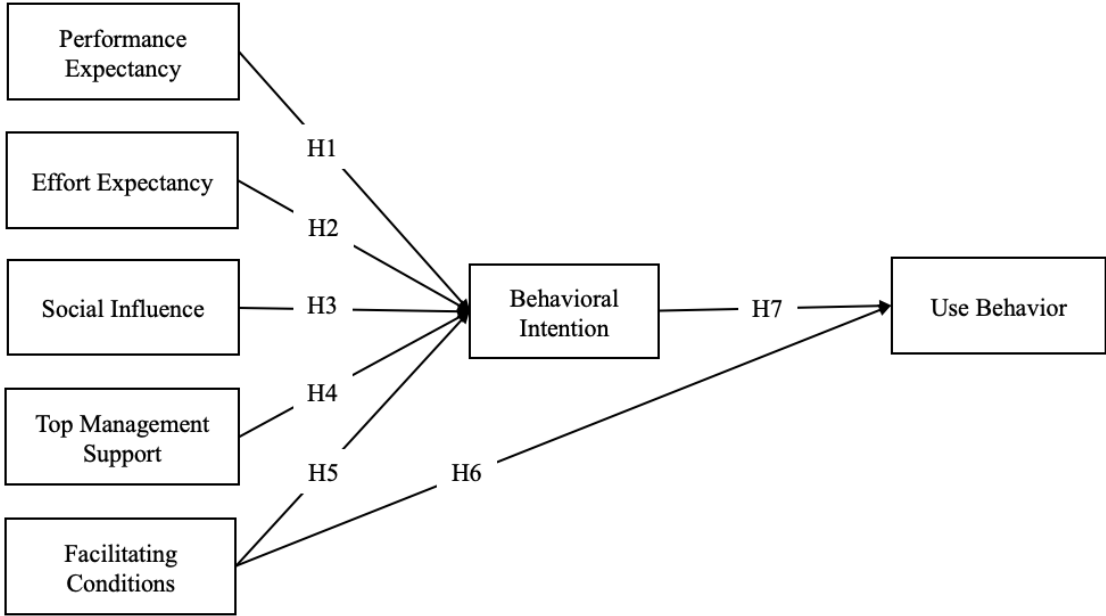

Figure 1. Research model

The proposed research model includes variables in the Unified Theory of Technology Acceptance and Acceptance (UTAUT), adding the variable "Top Management Support" proposed, published by Wu et al. (2003). The authors propose that Performance Expectancy, Effort Expectancy, Social Influence, Facilitating Conditions, and Top Management Support affect the behavioral intentions of users, thereby determining the behavior of users to apply technology. From there, the research hypotheses proposed by the authors:

H1: Performance Expectancy has an effect on Behavioral Intention to apply Blockchain technology.

H2: Effort Expectancy has an effect on Behavioral Intention to adopt Blockchain technology.

H3: Social Influence has an effect on Behavioral Intention to adopt Blockchain technology.

H4: Facilitating Conditions have an effect on Behavioral Intention to adopt Blockchain technology.

H5: Top Management Support has an effect on Behavioral Intention to apply Blockchain technology.

H6: Facilitating Conditions have an effect on Use Behavior.

H7: Behavioral Intention to adopt Blockchain technology has an effect on Use Behavior.

3. Method

The research team clarified the issues raised through two phases. In the first stage, the research team builds the model and preliminary scales. Then, the team conducted in-depth interviews with 15 individuals currently working at Logistics enterprises that have been applying Blockchain technology. The qualitative research results are the basis for the research team to verify the quality of the scales, and adjust and complete the questionnaire. Then, the authors continued to test the adjusted questionnaire with 116 respondents. At the end of phase 1, the authors used quantitative survey results to test the reliability of the scale reliability and validity through Cronbach's Alpha and Confirmatory Factor Analysis CFA to continue to adjust the questionnaire before it was available.

In the second stage, the authors conducted large-scale formal quantitative interviews. The official questionnaire is divided into two parts, the first part is demographic information including gender, age, education level, and several years of experience. The second part is the structured questionnaire which studies the factors influencing the adoption of Blockchain technology. There are 44 questions and each scale is measured on a 5-point Likert scale.

About the optimal sample size, Gorsuch (1983) suggested that the number of samples should be 5 times larger than the number of observed variables to ensure reliability. Since the number of observed variables is 44, the minimum sample size required to ensure reliability and stability when studying the factors affecting the application of Blockchain technology in Logistics enterprises is 220. The authors conducted a survey and collected 508 samples. Survey subjects are randomly selected

from Logistics enterprises that have been applying Blockchain technology in Vietnam. It ensures randomness and limits possible biases.

Of the 508 valid responses, the majority of participants were female, with an average age of 18-25 years old. Regarding the experience of the participants, 57.9% have less than 5 years of experience, 27.8% have 5-10 years of experience, and the rest have more than 10 years of experience. Most of the respondents are staffs or expert, with a rate of 74.6%, following by Team Leader/Head of Department/Manager (17.9%) and Board of Directors/Director/President (5%).

4. Results

4.1. Measurement of Reliability and Validity

The reliability of the scales was tested through Cronbach's Alpha coefficient. According to Hair et al. (2014) have shown that with Cronbach's Alpha coefficient, if it is in the range [0.7, 0.8], it means that the scale is good, and with the coefficient $\alpha \geq 0.06$, the scale is eligible to use (acceptable in terms of reliability).

After conducting the test of scale reliability and obtaining a Cronbach's Alpha coefficient of over 0.6 for all factors, as well as all Corrected Item-Total Correlation coefficients being greater than 0.3, the conclusion can be drawn that all scales are suitable for being retained in the Exploratory Factor Analysis (EFA) analysis.

Based on the Rotated Component Matrix factor rotation table, all factor loading coefficients are greater than 0.5, ensuring their significance. Therefore, no variables are excluded. The Eigenvalue coefficient is $1.000 \geq 1$, representing the proportion of variance explained by each factor. This indicates that the extracted factors effectively summarize the information. The total variance extracted, as represented by the Extraction Sums of Squared Loadings (Cumulative %), is 72.243%, which is greater than 50%. This indicates that the six independent factors explain 72.243% of the research model.

The convergent validity shows whether the observed variables of a latent variable are positively correlated with each other and how strong the positive correlation is. To evaluate the convergent validity, the team considers the external load coefficients of the observed variables, as well as the average extracted variance (AVE), where the AVE value needs to be greater than 0.5 (Hair et al., 2014). In this study, the AVE values of the variables reached above the threshold, except for the Facilitating Conditions variable whose AVE value was $0.3 < 0.5$. However, the authors believed that the elimination of this factor is not necessary. It is because the formula for calculating AVE (Average Variance Extracted) does not take into account the contribution of each indicator but rather focuses on representativeness. If the observed variables set any variable with a normalized factor loading less than 0.7, but the remaining observed variables have high factor loadings and are included in the AVE calculation formula, the index is still guaranteed to be 0.5 or higher, demonstrate the overall convergence of the measurement scale.

Table 1. Measurement of Reliability and Validity

Construct	Item	Cronbach's alpha	Factor loadings	Composite reliability	AVE
Performance Expectancy	PE1	0.658	0.747	0.839	0.511
	PE2	0.679	0.814		
	PE3	0.611	0.739		
	PE4	0.597	0.784		
	PE5	0.657	0.806		
Effort Expectancy	EE1	0.743	0.869	0.799	0.500
	EE2	0.681	0.821		
	EE3	0.641	0.775		
	EE4	0.798	0.898		
Social Influence	SI1	0.725	0.818	0.878	0.514
	SI2	0.756	0.822		
	SI3	0.768	0.855		
	SI4	0.694	0.896		
Facilitating Conditions	FC1	0.703	0.862	0.848	0.390
	FC2	0.659	0.823		
	FC3	0.755	0.920		
Top Management Support	TMS1	0.765	0.823	0.891	0.537
	TMS2	0.746	0.849		
	TMS3	0.754	0.903		
	TMS4	0.778	0.873		

To measure the distance between latent variables, the team continued to test discriminant validity. The discriminant index in all variables is larger than the correlation values of the corresponding latent variables, showing that the discriminant validity test results are statistically significant.

Table 2. Discriminant Validity

	BE	PE	EE	TMS	SI	FC	IN
BE	0.796						
PE	0.461	0.714					
EE	0.234	0.245	0.791				
TMS	0.495	0.229	0.254	0.820			
SI	0.340	-0.008	0.160	0.533	0.802		
FC	0.585	0.255	0.162	0.623	0.500	0.806	
IN	0.795	0.402	0.341	0.630	0.506	0.586	0.808

4.2. Hypothesis testing

After conducting a reliability analysis of the measurement scale using Cronbach's Alpha, exploratory factor analysis (EFA), and confirmatory factor analysis (CFA), the research team proceeded with structural equation modeling (SEM) to test the hypotheses.

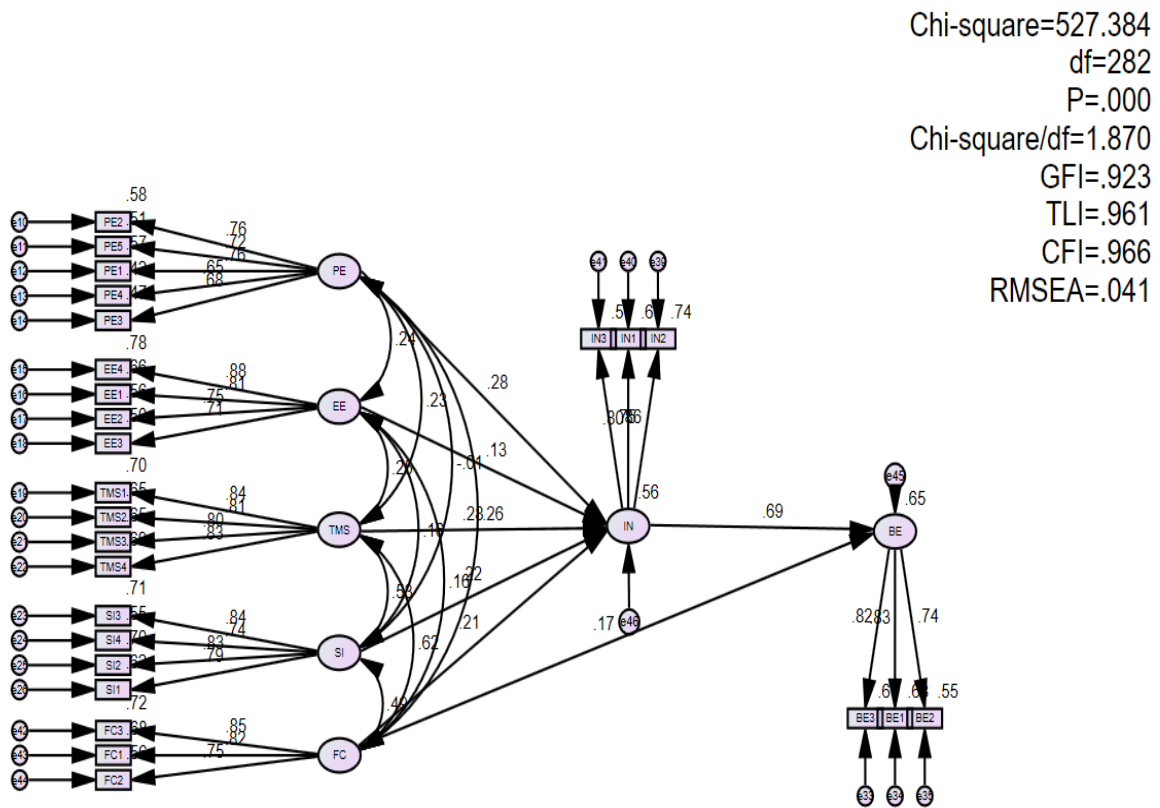

Figure 2. Result of SEM analysis

The SEM analysis provides the model fit index as follow:

- Chi-square/df = 1.870 < 2
- TLI = 0.961 > 0.9
- CFI = 0.966 > 0.9
- GFI = 0.923 > 0.9
- RMSEA = 0.041 < 0,08

Based on the analysis of the Model Fit index using SEM software, the authors concluded that the model is consistent with the theory and the data collected from our previous research. The researchers then proceeded to test the hypothesis of the impact of independent variables on "Behavioral Intention" and "Use Behavior".

After examining the mediating variable "Behavioral Intention" (IN), it can be observed that all independent factors (PE, EE, TMS, SI, FC) have a P-value less than 0.05. Therefore, these independent factors have a positive impact on the dependent variable (IN) and this relationship is positive as the signs of the relationships are all positive. These

independent factors explain 56.5% of the variance in behavioral intention (considered the Standardized Regression Weights)

Regarding the applied behavior, it can be seen that both independent factors (IN, FC) have a P-value less than 0.05. Therefore, both independent factors (IN, FC) have an impact on the dependent variable (BE) and this relationship is positive as the signs of the relationships are all positive. These independent factors explain 65.1% of the variance in applied behavior (considered the Standardized Regression Weights).

After all the tests performed, the authors obtained the following results of the hypothesis testing as in the table:

Table 3. The result of hypothesis testing

No.	Hypothesis	Test result
H1	Performance Expectancy has an effect on Behavioral Intention to apply Blockchain technology.	Supported
H2	Effort Expectancy has an effect on Behavioral Intention to adopt Blockchain technology.	Supported
H3	Social Influence has an effect on Behavioral Intention to adopt Blockchain technology.	Supported
H4	Facilitating Conditions have an effect on Behavioral Intention to adopt Blockchain technology.	Supported
H5	Top Management Support has an effect on Behavioral Intentions to adopt Blockchain technology.	Supported
H6	Facilitating Conditions have an effect on Use Behavior.	Supported
H7	Behavioral Intention to adopt Blockchain technology has an effect on Use Behavior.	Supported

5. Discussion and Conclusion

5.1. Discussion

The results of this study show that there are six factors affecting the application of Blockchain technology in Logistics enterprises in Vietnam, including Performance Expectancy, Effort Expectancy, Social Influence, Facilitating Conditions, and Top Management Support.

The Performance Expectancy factor has the most impact on the intention to adopt Blockchain technology, with an influence of 32.1%. This shows that in applying technology, individuals are most interested in the possibility that Blockchain technology can help them improve and enhance their work efficiency. Users place the highest expectations on the ability to save costs and improve the online transaction capacity of Blockchain technology. This result is consistent with previous studies by Gausdal, Czachorowski, and Solesvik (2018), Li (2019), Jagtap et al. (2020), and Dowelani, Okoro, and Olaleye (2022). These

authors argue that Blockchain technology makes a great contribution to reducing administrative costs as well as coordinating Logistics activities.

It is worth noting that the Top Management Support factor, which was further suggested by the researchers, has the second largest influence on behavioral intention, with a level of 23.8%. Management's support is reflected in the willingness to participate in the transition and adoption of technology, take risks during the testing process, communicate with employees to understand the need for adoption, and consider Blockchain as a resource to create competitive advantages for businesses. Compared with the previous research results of Orji et al. (2020), Bekrar et al. (2021), and Bag et al. (2022), the above authors also confirmed that top management support is an important factor affecting the application of Blockchain technology in the Logistics industry. The active participation in each stage of the digital transformation process and the application of technology by leaders and managers in Logistics businesses will help provide direction and meet the necessary support requirements in and after the application process (Clohessy and Acton, 2019).

The factors Social Influence, Facilitating Conditions, and Effort Expectancy have a positive influence on behavioral intention to apply Blockchain technology, with the influence level of 20.2%, 19.1%, and 11.1%, respectively. It shows that when employees perceive that colleagues in the same working environment show a positive attitude when applying Blockchain technology, they will be motivated to apply this technology in their work. In addition, to promote the application of Blockchain technology, businesses need to focus on preparing favorable conditions such as infrastructure or equipping employees with knowledge. In addition, Facilitating Conditions can also directly affect adoption behavior with a level of 15.3% on adoption behavior. It is consistent with previous studies. The previous research of Venkatesh (2003) built two hypotheses about the impact of Facilitating Conditions on Adoption Behavior. Even in the work of Thompson (1991) and Venkatesh (2000) Facilitating Conditions even have no effect on predicting Behavioral Intention but directly affect Use Behavior.

Finally, the results of the mean difference test show that individuals of different ages and experience groups will have different Use Behavior. It is consistent with the previous work of Venkatesh (2003). However, the study results showed that gender did not affect Use Behavior, which is different from the results of this study. It may be the influence of the social development process and cultural characteristics of Vietnam, as gender equality become more and more obvious (Nguyen, 2012; Dineen and Le, 2015). Therefore, the thoughts and opinions of the respondents may be less affected by prejudices or gender differences. Future studies may continue to explore and test whether there are differences between men and women in technology adoption.

The overall contribution of this study is to propose a comprehensive model based on applying Venkatesh's UTAUT model (2003), combined with the independent variable Top Management Support. Since then, the study has found the factors affecting the adoption of technology and at the same time indicated the degree of influence of each factor. Not only that, but the study also found that there is a difference in the technology adoption behavior

of respondents of different ages and experiences. This can suggest for administrators and executives deploy technology application plans to different target groups.

5.2. Implication

To deploy Blockchain technology effectively, it is necessary to successfully apply this technology in the management and operation of Logistic enterprises. A smart, simple, transparent, and fast management system will improve the operational efficiency of the business. Therefore, the research team gives some recommendations for Blockchain technology applications in business operations.

First, businesses should consider when choosing to apply Blockchain technology. It is necessary to consult with experts in the field of information technology, combined with the actual operation of enterprises to be able to apply technology appropriately. In addition, the application of Blockchain technology must take place synchronously, between departments and units to achieve consistency and avoid unnecessary deviations. Management needs to closely monitor the process of applying technology at different units in the company. Second, it is necessary to consider the application of Blockchain technology with trading partners from which to draw lessons for their businesses. Moreover, the top management board needs to pay attention to the application of Blockchain technology in the business. Employees should be encouraged to actively adopt the technology. Implement policies to support material or spiritual to motivate employees. Thereby achieving effective management as well as the dissemination of Blockchain technology.

5.3. Limitations and Recommendations

The research has set clear goals, which have been explored and solved by the authors, but there are limitations and difficulties that the group encountered. Firstly, research data may not guarantee coverage and a broad spectrum. The main reason for this limitation is that Blockchain technology is not popular in Vietnam, especially in the production and business activities of Logistics enterprises. Secondly, the group has learned a lot about the factors that can affect the behavior of applying Blockchain technology to the business activities of Logistics enterprises. However, the researchers found that, besides the theoretical bases that we researched, there are still many factors that can affect the behavior of applying Blockchain technology in practice. Further research is needed based on practice specifically based on the business activities of Logistic enterprises.

The existing limitation is also an important gap as well as a foundation for further research related to Blockchain technology. In the future, work can be done with different sizes and spaces so that the research topic can be completed in a more detailed and objective way. Research development direction can be specified in terms of research scale and space. Thereby, studies should also clearly show how the denominators with different scales and spatial scales affect and differ. At the same time, the measurement scales also need to be clearly and correctly defined for more accurate research. Further studies can also apply the Blockchain model in this study to other fields or topics besides Logistics.

5.4. Conclusion

Based on the UTAUT model, combined with the variable 'Top Management Support', this study tried to investigate the factors affecting the application of Blockchain technology in Logistics enterprises in Vietnam. The results show that Performance Expectancy, Effort Expectancy, Social Influence, Facilitating Conditions, and Top Management Support influence the Behavioral Intention of individuals in adopting Blockchain technology. Besides, not only Behavioral Intention but Facilitating Conditions can also directly affect the Use Behavior of respondents. Therefore, this study will help technology developers and businesses better understand the behavioral characteristics of individuals in applying Blockchain technology and encourage Logistics businesses to understand the importance of Blockchain technology. These findings provide valuable information for governments, businesses, and individuals promoting Blockchain technology adoption in Logistics operations.

Abstract

The research aims to analyze and evaluate the factors influencing the decision to use mobile payment of Northern Vietnamese university students. The article uses a combined research model, inherited from the Technology Acceptance Model (TAM), Unified Theory of Acceptance and Use of Technology (UTAUT), Theory of Planned Behavior (TPB), and previous studies. The research uses a combined qualitative and quantitative method based on data collected from 327 observations. The results show that Perceived Usefulness (PU) has the strongest impact on the decision to use mobile payment among Northern Vietnamese university students, followed by Perceived Security (PS), Social Influence (SI), Perceived Ease of Use (PEOU), Perceived Behavioral Control (PBC), and Trust (T). With these results, the study highlights the importance of paying attention to the above factors when formulating policies, building promotional campaigns, and operating mobile payment technology.

Keywords: *decision, mobile payment, student, technology.*

1. Introduction

The rapid development of technology and internet services in such an globally integrated economy is considered to be the driving force behind mobile phones' popularity. This device is becoming an effective tool with many features that integrate online products

and services (Bauer, Reichardt, Barnes & Neumann, 2005; Hsu & Kulviwat, 2006; Varshney & Vetter, 2002). The development of e-commerce opens up a new platform that meets the divergent needs of customers (Skeldon, 2011), in which mobile payments make an important contribution as leverage for the rise of e-commerce. Mobile payments allow people to make money transfers quickly and conveniently (Mallat, Rossi & Tuunainen, 2004). Technological gadgets such as e-banking are gradually gaining consumer acceptance (Barutcu, 2008; Xu, Teo, Tan & Agarwal, 2009). But it's online payments' popularity that really roared after the pandemic. Hence, the question for businesses providing mobile payment services is what factors significantly contribute to the decision to use mobile payments? Therefore, exploring the factors influencing decision to use mobile payment is essential (Dahlberg, Mallat, Ondrus & Zmijewska, 2008). Regulators and researchers are focusing on navigating the use of mobile payments in e-commerce because it can greatly benefit commercial organisations, payment service providers, software service providers, and third parties (Lim, 2008 and Ondrus & Pigneur, 2006). As such, mobile payment has become a widely contested topic in the world. However, the number of studies on factors affecting the decision to use mobile payment has recently been insufficient in Vietnam.

The structure of the article consists of five parts: (1) Introduction, (2) Literature review and theoretical framework, (3) Research methodology, (4) Results and discussion, and (5) Conclusions and recommendations.

2. Literature Review and Theoretical Framework

2.1. Literature Overview

The study of knowledge about users' decision to use a technology, here is mobile payment, is always practical, especially in the 4.0 era. This is because understanding what factors users base their decision to use a device can help service providers continue to improve their own technology model, thereby building a more efficient technology ecosystem. Understanding this, many foreign researchers have chosen to use mobile payment as the main direction for their scientific work (Dahlberg et al., 2015). When studying mobile payments, Slade, Williams, & Dwivedi (2013) categorised researches into three main areas, including: research on decision-making and usage behaviour of mobile payments; research on the development, classification, evaluation, and comparison of mobile payment types or between mobile payments and other payment methods; and market analysis research on mobile payments.

Studies relating to factors influencing decision to use mobile payment typically employ the Technology Acceptance Model (TAM) when examining mobile payments (de Luna & colleagues, 2020; Nguyen, Cao, Dang, & Nguyen, 2016). Additionally, the Theory of Reasoned Action (TRA), the Theory of Planned Behavior (TPB), and the Unified Theory of Acceptance and Use of Technology (UTAUT) are also often ubiquitously used (Abrahão, Moriguchi, & Andrade, 2016; de Luna & colleagues, 2020). For instance, de Luna and colleagues combined theories from the TAM, TRA, and TPB to propose a research model (de Luna et al., 2020). However, there are also some less commonly used theories, which

limit the depth of investigation into the factors impacting mobile payment usage. This is a major limitation that few studies have addressed, which creates a research gap that needs to be filled in the future.

Factors can be categorised into three groups: user-related factors, technology-related factors, and environmental factors (Oliveira, Thomas, Baptista, & Campos, 2016). Regarding user characteristics, trust in a technological system is a critical factor (Shankar & Datta, 2018). For example, when a user has trust in an online payment system from a service provider, that user is likely to choose the mobile payment service of that provider due to the established trust (Cao, Yu, Liu, Gong, & Adeel, 2018). In addition, regarding technology-related factors, a study suggests that mobile payment promotion campaigns should focus on emphasising the applicability of this technology, such as quick payment during shopping, transaction security, and increased efficiency. Regarding environmental factors, a study on mobile payment adoption in Malaysia suggests that cultural factors should be emphasised (Hiram, Yusman, Lona, Wee, 2015).

However, there still exist some limitations in the previous published studies. The most common limitation is the demographic nature of study samples (de Luna et al., 2020; Shankar & Datta, 2018). Additionally, other limitations can be identified, such as the restriction in selecting factors for investigation (Abrahão, Moriguchi, & Andrade, 2016), or relatively small sample sizes compared to the total number of payment service users (Cao et al., 2018). Therefore, the emergence of studies examining different impacting factors and diverse demographic characteristics of surveyed samples is necessary, as this is a limitation that is difficult to resolve due to the barrier of collecting and statistically analysing information on a large scale. Moreover, it is because of the infinite nature of knowledge that cannot be encapsulated in a single study.

2.2. Mobile Payments

Clarifying the definition of mobile payment holds great primacy when investigating the decision to use this payment method. Mobile payment (m-payment), firstly, is a form of online payment. It is defined as a transaction activity in which at least one stage is carried out by a mobile device capable of conducting financial transactions securely via mobile networks or wireless technologies (Ghezzi, Renga, Balocco, and Pescetto, 2010). In particular, this service allows users to solve their need for cash at checkout (Pham & Ho, 2015). Thus, it can be said that the introduction of mobile payment systems benefits both providers and consumers (Oliveira, Thomas, Baptista, Campos, 2016).

Mobile payment transactions can be classified into 5 main directions: Business to Business (B2B), Business to Customer (Business to Consumer - B2C), Customer to Customer (Consumer to). Consumer - C2C), Business to Government (B2G), and Person to Person (P2P) (Singh & Jasmine, 2012).

For B2B mobile payments, there are three types of payment systems: alternative payments for the traditional services of banks or financial companies, payments made in conjunction with banks and financial companies to provide services to end users, and pay

using the ACH system (Valcourt, Robert, & Beaulieu, 2005). In Vietnam, a number of B2B payment systems, including mobile banking applications, are widely available. Regarding mobile payments between Business and Customers (B2C), it is necessary to mention the payment methods of e-commerce platforms. This process includes stages: customers collect information, pay for physical goods or informational goods, and then receive goods. Some units that develop this type of payment in Vietnam may include Shopee, Grab, or Lazada. For mobile Customer-to-Customer (C2C) transactions, such transactions typically take place between end users through an enterprise platform created for transactions (Singh & Jasmine, 2012). In terms of B2G mobile payments, web-based payment policies increase the clarity of payment processes and reduce the risk of duplication. And finally, P2P mobile payments are transactions between two individuals and are often SMS-based.

There are many methods of making mobile payments. In essence, a GSM mobile device can send or receive information (mobile data service) through three channels including SMS, USSD or WAP/GPRS. Channel choice impacts how mobile payment programs are implemented (Singh & Jasmine, 2012). Talking about mobile payment methods, the first thing to mention is SMS - Short Message Service. SMS is used to provide transaction or account status information (Singh & Jasmine, 2012). Furthermore, Unstructured Supplementary Service Data (USSD) can be mentioned. Regarding WAP (Wireless Application Protocol) and GPRS (General Packet Radio Service), Internet services are provided through these gateways, through which mobile payments are made. Another form of mobile payment method can include payment via QR code. A QR code is a storage system that uses a dot matrix or two-dimensional barcode. Alternatively, QR codes can be printed or displayed on a screen and interpreted by a special reader (Denso Wave, 2000) to provide more information than traditional barcodes. In addition, there are a number of other methods to make mobile payments such as NFC (Near Field Communication) or e-wallets (Mobile Wallet).

Mobile payments can be categorized into a number of distinct types. Transactions made at the Point of Sale (POS) are the first type of mobile payment (Valcourt et al., 2005). The consumer can use this method at the point of sale (POS) to pay with a mobile phone. Customers must be able to synchronize with the merchant system in order to complete a transaction. In situations where the customer has run out of currency, mobile devices at the point of sale are helpful for micropayments. The mobile phone must be able to communicate with the merchant system, which is a drawback of this strategy. Mobile platforms are yet another type of mobile payment (Stiller et al., 2012). The fundamental benefit of this approach is that customers can make purchases at a virtual point of sale whenever and wherever they want. It is a mobile-based extension of internet commerce (Valcourt et al., 2005). In the past, a disadvantage of this mobile payment form is that the current mobile phone technology is not 100% appropriate to mobile commerce (Valcourt et al., 2005). However, as technology continues to evolve, it is observed that this type of mobile payment is getting more holistic day by day. There are also several other types of mobile payment, such as Direct Carrier Billing, or Closed Loop Mobile Payment (Stiller et al., 2012).

2.3. Factors influencing the decision to use mobile payments and research hypotheses

There are many factors that have been proven to influence a person's decision to use mobile payments. The majority of these factors are derived from several study models or from the observations of researchers. The primary and most empirically supported factors are Perceived Ease of Use (PEOU), Perceived Usefulness (PU), Trust (Trust), Perceived Security (PS), Perceived Risk (PR), and Social Influence (SI) or Social Influence (SI) (Karsen, Chandra & Juwitasary, 2019). For example, Perceived Ease of Use (PEOU) is defined as the ease with which a person perceives to be familiar with using a type of technology. Perceived Ease of Use is thought to have a rapid and indirect influence on intention to use a technology through Perceived Usefulness (PU) (Kim, Mirusmonov & Lee, 2010). This is a factor that has been shown to influence the decision to use mobile payments in various studies. In addition, there are also a number of researched factors that have an impact on Perceived Ease of Use (PEOU), thereby indirectly affecting the decision to use mobile payments. Liu et al (2019) demonstrated that Perceived Mobility has a direct positive impact on Perceived Ease of Use (PE). In addition, user-subjective factors also affect Perceived of Ease of Use (PE). Subjective factors can be mentioned such as Innovation and M-payment Knowledge (Kim, Mirusmonov and Lee, 2010).

There are many factors that have been shown to have an impact on users' decisions to use mobile payments. These factors are mostly derived from various research models or through the observation of researchers. In general, the main factors that have been most frequently mentioned and studied are: Perceived Usefulness (PU), Perceived Ease of Use (PEOU), Social Influence (SI), Perceived Behavioral Control (PBC), Perceived Security (PS), and Trust (T).

2.3.1. Perceived Usefulness (PU)

Perceived Usefulness (PU) is defined as the degree of improved performance that a person perceives they will attain by accepting the use of a technology (Kim, Mirusmonov & Lee, 2010). Davis (1989) states that the trend of using a service or an information technology device can largely be predicted by Perceived Usefulness. Furthermore, previous studies have shown that Perceived Usefulness has a direct and significant impact on the decision to use mobile payment services (de Luna et al., 2020; Shankar & Datta, 2016). Therefore, the research team hypothesised that Perceived Usefulness (PU) has a positive impact on the decision to use mobile payment services among students in the Northern region of Vietnam. Thus, the proposed research hypothesis is:

H1. Perceived of usefulness (PU) has a positive impact on the decision to use mobile payment among Northern Vietnamese undergraduate students.

2.3.2. Perceived Ease of Use (PEOU)

Perceived Ease of Use (PEOU) is defined as the degree of ease with which a person perceives becoming familiar with the use of technology. Perceived ease of use is believed to have a quick and indirect impact on the intention to use technology through Perceived

Usefulness (PU) (Kim, Mirusmonov & Lee, 2022). Many studies have shown that Perceived Ease of Use has an impact on the decision to use m-payment by users (Chen and Lei, 2008; Kit, Jenn, & Kelly, 2018). Therefore, the authors hypothesize that Perceived Ease of Use (PEOU) has a positive impact on the decision to use mobile payment services by users. Accordingly, the proposed research hypothesis is:

H2. Perceived Ease of Use (PEOU) has a positive impact on the decision to use mobile payment among Northern Vietnamese undergraduate students.

2.3.3. Social Influence (SI)

Social Influence (SI) refers to the degree to which users perceive that important others (e.g., family, friends) believe they should use a technology (Venkatesh, 2012). It reflects the influence of environmental factors such as the opinions of a friend, relative, and superior on behavior (Venkatesh et al., 2003). Previous studies have shown that Social Influence has a direct impact on the decision to use m-payment (Abrahão, Moriguchi, & Andrade, 2016; Lin, & Ding, 2020); therefore, the authors hypothesize that this factor also has a positive impact on the decision to use mobile payment services among students in the northern region. Accordingly, the proposed research hypothesis is:

H3. Social Influence (SI) has a positive impact on the decision to use mobile payment among Northern Vietnamese undergraduate students.

2.3.4. Perceived Behavioral Control (PBC)

Perceived Behavioural Control (PBC) is a factor developed in the Theory of Planned Behavior (Ajzen, 1988), which influences both the intention to perform a behavior and the actual behavior. PBC has been shown to have an impact on the decision to use mobile payments in various studies (Ting, Yacob Liew & Lau, 2016; Sun, Law, & Schuckert, 2020). Therefore, the authors hypothesize that this factor also has a positive effect on the decision to use mobile payment services among students in the Northern region. The proposed research hypothesis is:

H4. Perceived behavioral control (PBC) has a positive impact on the decision to use mobile payment among Northern Vietnamese undergraduate students.

2.3.5. Perceived Security (PS)

For mobile payment services, Perceived Security (PS) refers to the extent to which a person believes that transactions through this service are secure in terms of both financial and personal information (Hartono et al., 2014). Perceived Security has been shown to have an impact on the decision to use mobile payment (Zhang, Luximon, & Song, 2019; Wai & Wing, 2019). Therefore, the authors believe that this factor has a positive impact on the decision to use mobile payment services among students in the Northern region. Accordingly, the proposed research hypothesis is:

H5. Perceived of security (PS) has a positive impact on the decision to use mobile payment among Northern Vietnamese undergraduate students.

2.3.6. Trust (T)

Trust (T) can be defined as a positive expectation of consumers toward a service provider (Mayer, Davis & Schoorman, 1995). For electronic services, Trust is considered the most essential factor influencing users' perceptions (Mallat, 2007). For mobile payment services, several studies have also demonstrated the impact of this factor on users' adoption decisions (Shankar & Datta, 2018; Cao et al., 2018). Based on this, the authors believe that Trust has a positive effect on users' decision to use mobile payment services. Therefore, the research hypothesis is proposed as follows:

H6. Trust has a positive impact on the decision to use mobile payment among Northern Vietnamese undergraduate students.

2.4. Model recommendation

Based on the theories and hypotheses mentioned above as well previous related studies, the proposed research model is as follows:

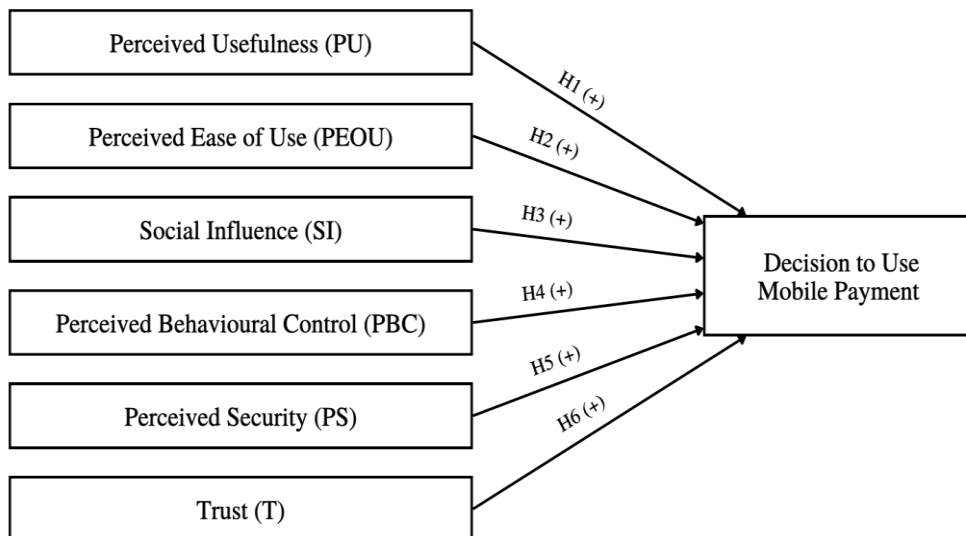

Figure 1. Proposed Research Model

Source: Authors proposed

3. Method

3.1. Data collection methods and research samples

3.1.1. Data collection

The authors chose to investigate Northern Vietnamese undergraduate students to study factors affecting their decision to use mobile payment for some reasons. Firstly, Northern Vietnamese undergraduate students are a large community ensuring that the authors have enough data samples to evaluate and analyze the factors. Secondly, in Northern Vietnam, there are many large companies, businesses, as well as big stores, supermarkets, and shopping centers, this can create a favorable environment to collect information and user data on mobile payments.

The main method used in the research project is the quantitative research method, aiming to evaluate the correlation between factors and the decision to use mobile payment of Northern Vietnamese undergraduate students. The content of the quantitative research method presented by the authors includes (1) Research model and hypothesis, (2) Scale development and survey questionnaire, (3) Quantitative research design and sample, (4) Data collection, (5) Data analysis.

The questionnaire was designed on Google Forms and sent to survey subjects via social networks. With this method, the authors obtained 350 answer votes. However, of those, 23 respondents were disqualified due to incorrect respondents or uncooperative respondents (with the same answers to all questions or questions with opposite meanings). After the unsatisfactory questionnaire was eliminated, 327 questionnaires were formally put into data processing.

After distributing survey forms, the research group received 350 responses. Among the 350 responses, 53.14% were female and 46.86% were male. The survey respondents were mainly aged from 18 to 26 years old, with the highest proportion being the age group from 18-20 years old (51.1%), followed by the age group from 21-23 (42.3%), then the age group under 18 years old (4.9%), from 24-26 years old (1.4%), and the age group over 26 years old accounted for only 0.3% of the total study population.

3.1.2. Research sample

Clarification of the number of samples is extremely necessary to increase the accuracy of the study results. The sample size depends on many factors such as the processing method (regression analysis, EFA discovery factor analysis,...), and reliability,... To use EFA exploratory factor analysis, large sample sizes are usually determined based on the minimum size and number of measurement variables included in the analysis (Nguyen Dinh Tho, 2013). Multivariate regression analysis achieves the best results, the sample size must satisfy: $n \geq 8k + 50$ (where n is the sample size and k is the number of independent variables) (Tabachnick & Fidell, 1996). Meanwhile, Hair et al. (1998) estimated that the number of samples needed was 5 times the number of variables, while Hoang Trong & Chu Nguyen Mong Ngoc (2008) suggested that the ratio was 4 or 5. In this study, the sample size was scaled so that the multivariate regression model makes sense. There are 29 variables in which factor analysis is required, so the minimum sample size required is $29 \times 5 = 145$ observations.

To ensure the reliability of the study results, the authors developed an initial sample of 327 questionnaires. This number of observations both satisfies the sample size requirement and is similar to some similar studies in the same field as the study. The survey was conducted in the North of Vietnam, the respondents were students of universities and colleges in the North of Vietnam, mainly aged 18-26 years, young people who can access information technology early and are sensitive to changes in the times, so the authors consider this a reasonable choice.

3.2. Survey construction

The authors proceeded to develop study measurement:

The Likert 5 scale, from a score of 1 (strongly disagree) to a score of 5 (strongly agree) is used to measure factors that impact mobile payment intent for 6 related variables: Perceived Usefulness (PU), Perceived Ease Of Use (PEOU), Social Influence (SI), Perceived Behavioral Control (PBC), Perceived Security (PS), and Trust (T) inherited and developed from the research of de Luna & cộng sự, 2020; Shankar & Datta, 2016; Kim, Mirusmonov & Lee, 2022; Humbani & Wiese, 2019; Nguyễn, Cao, Đăng, Nguyễn, 2016.

Scale development process:

From the results summarised in the previous sections on the research overview, theoretical basis and qualitative research, the authors proposed a formal research model. To fit the proposed model and research goals, the authors develop the scale following these steps:

- Overview of related studies.
- Qualitative research.
- Preliminary quantitative study on 20 students in the North of Vietnam on factors influencing the decision to use mobile payments.
- Complete the scale for formal quantitative research.

Thus, the authors synthesize the survey items according to the variables and previous scales as follows:

Table 1. Summary of research variables, indicators, scales, and origins

Element	Observation variables	Source	Encode
Perceived usefulness	1. Mobile payments make it easier for me to pay so I decided to use mobile payments.	Bhattacharjee (2001), Devaraj et al. (2002), van der Heijden (2003)	PU
	2. Mobile payments allow me to make payments at a higher speed, so I decided to use mobile payments.		
	3. Mobile payments give me more purchase options, so I decided to use mobile payments.		
	4. Mobile payment is a useful service, so I decided to use mobile payment.		

Element	Observation variables	Source	Encode
Perceived Ease of Use	1. Mastering mobile payments was easy, so I decided to use mobile payments.	Bhattacharjee (2001), Davis (1989), Taylor & Todd (1995), Venkatesh & Davis (2000)	PEOU
	2. The method of using mobile payments is clear and easy to understand, so I decided to use mobile payments.		
	3. The steps of paying via mobile payment were easy to follow so I decided to use mobile payments.		
	4. The steps of using mobile payment are easier to follow than other payment methods so I decided to use mobile payment.		
	5. Making transactions for different sectors became easier with mobile payments so I decided to use mobile payments.		
	6. I found mobile payments easy to manipulate, so I decided to use mobile payments.		
	7. I found mobile payments clear and easy to understand so I decided to use mobile payments.		
Social Influence	1. My relatives advised me to use mobile payment so I decided to use mobile payment.	Taylor & Todd (1995), Venkatesh & Davis (2000), Srinivasan (2015); Edwards & Eriksson (2014)	SI
	2. My relatives felt that using mobile payments brought many benefits so I decided to use mobile payments.		
	3. Friends who I know advised me to use mobile payments so I decided to use mobile payments.		

Element	Observation variables	Source	Encode
	4. Websites and social networks encourage the use of mobile payment, so I decided to use mobile payment.		
Perceived Behavioural Control	1. I have enough knowledge and skills to use mobile payments so I decided to use mobile payments.	Kim & Kim (2022); Pavlou & Fygenon (2006); Venkatesh & Zhang (2010); Venkatesh et al. (2012)	PBC
	2. I have the ability to decide my own transactions when using mobile payments so I decide to use mobile payments.		
	3. I believe that mobile payments can be used well so I decided to use mobile payments.		
	4. I intend to use mobile payments so I decided to use mobile payments.		
	5. I want to make mobile payments in the near future so I decided to use mobile payments.		
Perceived Security	1. I felt safe sending sensitive information via mobile payment so I decided to use mobile payment.	Cheng, Lam, & Yeung (2006); Luarn & Lin (2005), Parasuraman & Associates (2005)	PS
	2. I felt comfortable providing personal information via mobile payment so I decided to use mobile payment.		
	3. Mobile payments are secure enough to store sensitive information so I decided to use mobile payments.		
	4. Mobile payments are highly secure so I decided to use mobile payments.		

Element	Observation variables	Source	Encode
	5. The risk of exposing my mobile payment account information is low so I decided to use mobile payments.		
	6. The risk of being monitored by a third party when using mobile payments is low so I decided to use mobile payments.		
Trust	1. The mobile payment system is reliable so I decided to use mobile payments.	Kim et al. (2022)	T
	2. I believe that mobile payment providers will do what they promise, so I decided to use mobile payment.		
	3. I believe that mobile payment providers value users' opinions, so I decided to use this service.		

3.3. Data analysis methods

To research the decision to use mobile payments, this study encodes and enters official questionnaire data, then processes it using SPSS software version 22. Descriptive statistical methods used frequency statistical analysis to characterise the demographic characteristics of the sample: gender, age, education level, and income. The numbers from the remaining variables are analysed through steps: Cronbach's Alpha scale reliability test, EFA discovery factor analysis, correlation analysis, and linear regression analysis.

Step 1: Verify the reliability of the scale: If Cronbach's Alpha is greater than or equal to 0.6 and the overall correlation coefficient of the variable is greater than 0.3, that scale is reliable for further testing (Nunnally and Bernstein, 1994).

Step 2: The authors will conduct a factor analysis to explore EFA, to review and remove factors that do not fit the model. From there, the authors perform EFA tests with the following results should note as follows:

- The KMO value (Kaiser-Meyer-Olkin) is an indicator used to consider the appropriateness of factor analysis; it is necessary to reach a value from 0.5 to 1 as a condition for factor analysis to be appropriate.

- The Bartlett test is statistically significant (Sig. < 0.05) i.e. uses appropriate factor analysis.

- Eigenvalue greater than or equal to 1.

- Percentage of variance > 50%: Showing the percentage of variation of observed variables, i.e. whether the variation is 100%, how much the factor analysis explains. With a factor load factor of ≥ 0.5 , the observed variable was determined to be statistically significant (Hair et al., 2009). Variables that do not guarantee a load factor (< 0.5) will be eliminated (Othman & Owen, 2002).

Step 3: The authors use correlation analysis to better understand the correlation between variables and provide information about their relevance (D. R. Hardoon, S. Szedmak, and J. Shawe-Taylor, 2004). The Pearson correlation coefficient (r) is used to evaluate the linear relationship between the dependent variable and the independent variables. The value of r ranges from -1 to 1.

- If the Sig. value < 0.05 , the absolute value of r indicates how tight the linear relationship is.

- If the absolute value of r is as close as possible or -1, then the two variables are more closely correlated, and vice versa, moving towards 1 is a positive correlation, and towards -1 is a negative correlation.

- If $r = 1$ degree of absolute linear correlation.

- If $r = 0$ then there is no linear correlation, it is possible that there is no relationship between the two variables, or that there is a nonlinear relationship between them.

When the absolute value of r is large, it demonstrates that the relationship between the two variables is tighter and is suitable for using linear regression analysis. (Hoang Trong & Chu Nguyen, Mong Ngoc, 2008).

Step 4: After determining the linear relationship between two variables, we can use the linear scale method to model the causal relationship between them (Hoang Trong & Chu Nguyen Mong Ngoc, 2008). To test the research hypotheses and the degree of influence of the independent variables on the dependent variable, multivariate regression analysis with the Enter method and 95% confidence level are conducted. In addition, the evaluation indicators used include the corrected R-factor, which indicates the percentage of variability of the dependent variable that can be explained by the independent variables, the F-test to confirm the scalability of the h-model, and the T-test to refute the regression coefficient hypothesis of a population of zero.

4. Results

4.1. Scales evaluation

The results of Cronbach's Alpha coefficient analysis of the scales used in the topic are greater than 0.7 and the total variable correlation coefficient is greater than 0.4. With this result, no observed variables were eliminated. Thus, the scale of factors influencing the decision to use mobile payments including Perceived Usefulness (PU), Perceived Ease Of Use (PEOU), Social Influence (SI), Perceived Behavioral Control (PBC), Perceived Security (PS), and Trust (T) all meet the required reliability for subsequent analysis.

Table 2. Results of scale reliability assessment of research concepts

	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item - Total Correlation	Cronbach's Alpha if Item Deleted
1. Perceived Usefulness (PU): Cronbach's Alpha: $\alpha = 0.822$				
PU1	11.02	4.273	0.692	0.756
PU2	11.04	4.443	0.625	0.786
PU3	11.02	4.070	0.666	0.767
PU4	11.00	4.494	0.604	0.795
2. Perceived Ease of Use (PEOU): Cronbach's Alpha: $\alpha = 0.917$				
PEOU1	21.23	21.093	0.742	0.905
PEOU2	21.24	20.817	0.782	0.901
PEOU3	21.17	21.245	0.729	0.906
PEOU4	21.43	21.202	0.723	0.907
PEOU5	21.39	20.454	0.735	0.906
PEOU6	21.38	20.654	0.765	0.902
PEOU7	21.31	20.742	0.738	0.905
3. Social Influence (SI): Cronbach's Alpha: $\alpha = 0.761$				
SI1	11.40	6.045	0.409	0.746
SI2	11.04	6.348	0.589	0.693
SI3	11.24	5.738	0.567	0.701
SI4	11.11	6.107	0.608	0.680
4. Perceived Behavioural Control (PBC): Cronbach's Alpha: $\alpha = 0.772$				
PBC1	15.06	10.405	0.491	0.748
PBC2	15.10	9.984	0.601	0.710
PBC3	15.02	9.727	0.615	0.704
PBC4	14.80	11.287	0.429	0.766
PBC5	15.19	9.708	0.583	0.716

	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item - Total Correlation	Cronbach's Alpha if Item Deleted
5. Perceived Security (PS): Cronbach's Alpha: $\alpha = 0.924$				
PS1	16.16	18.776	0.782	0.910
PS2	16.16	18.705	0.798	0.908
PS3	16.31	18.228	0.755	0.913
PS4	16.37	18.209	0.775	0.910
PS5	16.28	18.019	0.766	0.912
PS6	16.30	17.721	0.812	0.905
6. Trust (T): Cronbach's Alpha: $\alpha = 0.860$				
T1	7.59	2.089	0.716	0.821
T2	7.61	2.152	0.756	0.785
T3	7.56	2.032	0.734	0.804

Source: Authors

Scales of 29 observed variables, after scale reliability verification using Cronbach's Alpha, are included in the EFA factor analysis.

The analysis of the EFA factor shows that there are 6 factors extracted at an Eigenvalue of 1.531 and the deduction variance of 66.426%. Moreover, $KMO = 0.915 > 0.5$ proves that the model is consistent with the data. KMO coefficient = $0.915 > 0.5$ also verifies that the EFA factor is relevant to the study. In addition, the individual load factor is more than 0.5, so the observed variables have good statistical meaning and are important in the factors, which have practical significance. $Sig.$ (Bartlett's Test) = $0.000 < 0.05$ demonstrate that observed variables are correlated in the population.

Table 3. Independent variable KMO and Bartlett test results

Factors	Result	Comparison
KMO coefficient	0.915	$0.5 < 0.915 < 1$
Sig. value in the Bartlett test	0.000	$0.000 < 0.05$
Extraction variance	66.426%	$66.426\% > 50\%$
Eigenvalue	1.531	$1.531 > 1$
Approx. Chi-square	4982.527	
df	406

4.2. Results Analysis

The regression results of factors influencing the decision to use mobile payments are presented in Table 4.

Table 4. Regression results

Model	Unstandardised Coefficients		Standardised Coefficients	t	Sig.	Collinearity Statistics	
	B	Std. Error	Beta			Tolerance	VIF
Constant	0.767	0.171		4.474	0.000		
PU	0.413	0.040	0.367	10.354	0.000	0.689	1.451
PEOU	0.158	0.037	0.158	4.262	0.000	0.632	1.583
SI	0.189	0.032	0.197	5.965	0.000	0.798	1.253
PBC	0.145	0.033	0.149	4.367	0.000	0.745	1.342
PS	0.226	0.031	0.253	7.214	0.000	0.704	1.421
T	0.129	0.035	0.119	3.730	0.000	0.855	1.170

Source: Authors

The authors used the Pearson coefficient to analyse the correlation between quantitative variables. The Pearson correlation coefficients between variables run from 0.136 to 0.680. This demonstrates the distinguishing value achieved, showing that the relationship between the dependent variable (MobilePayment Decision) and the independent variables is statistically significant (Sig. <0.05). Dependent variables impact the decision to use mobile payments is positively correlated with the variables Perceived Usefulness, Perceived Ease of Use, Social Influence, Perceived Behavior Control, Perceived Security, and Trust. So other statistics can be used to find the relationship between independent variables and dependent variables.

The linear regression equation with the dependent variable is the Decision to use mobile payments:

$$Y = 0.767 + 0.413PU + 0.158PEOU + 0.189SI + 0.145PBC + 0.226PS + 0.129T$$

Where:

PU: Perceived Usefulness

PEOU: Perceived Ease of Use

SI: Social Influence

PBC: Perceived Behavioural Control

PS: Perceived Security

T: Trust

Based on the normalised Beta coefficient, it was found that Perceived Usefulness factors had the strongest impact on mobile payment decisions (Beta = 0.413), followed by Perceived Security (Beta = 0.226), Social Influence (Beta = 0.189), Perceived Ease of Use (Beta = 0.158), Perceived Behavioural Control (Beta = 0.145), and Trust (Beta = 0.129). At the same time, the Sig. values of the factors are less than 0.05, and all hypotheses are accepted. Thus, the level of performance gains that North Vietnamese undergraduate students perceive will be achieved by adopting one type of technology (Kim, Mirusmonov & Lee, 2010) is extremely important, having a significant impact on this demographic's decision to use mobile payments. This result proved to Davis (1989) that the trend of using an information technology service or equipment can largely be predicted thanks to the perception of the usefulness of the product. However, North Vietnamese undergraduate students' trust, or positive expectations of a mobile payment provider (Mayer, Davis & Schoorman, 1995) did not have as significant an impact as Mallat (2007) or Yan & Colleagues (2009) stated.

5. Discussion and Conclusion

5.1. Implications

In terms of theoretical contribution, this study is tapping into a new research target with a model that has repeatedly proven effective. Currently, in Vietnam, the number of studies on mobile payment using models with similar factors is still not large. In addition, none of the studies focused on northern Vietnamese students. Hence, the authors believe that the study will expand the treasure trove of knowledge about user behaviour and intent toward using mobile payments. In addition, the model built in this study will provide directions to further research in the field of mobile payment, as well as knowledge related to users' decisions to use mobile payment in developing countries in general and Vietnam in particular. Moreover, considering practical implications, the authors believe that this study has provided basic information for mobile payment providers and the government to use for developing mobile payments. From the results of the study, the authors have provided more information about the factors affecting the decision to use mobile payment, helping mobile payment providers and the state and policymakers to refer to the development of mobile payment in general.

5.2. Recommendations

In Vietnam, mobile payment has tended to develop positively in recent years. More and more people are starting to use mobile payment apps. From the research results, the authors make some suggestions to improve the quality of mobile payment services in Vietnam, as well as attract new users, helping mobile payment service businesses expand domestically and internationally.

For the authority, taking the rise of mobile payment in consideration, an advent of a National Cybersecurity Association guided by the government is needed more than ever before. Given that cybersecurity is one of the most staggering threats to mobile payment providers and users, the government should create such an association in order to supervise

and assist security quality of service providers, as well as distribute information to users on cyber frauds targeting mobile payment transactions. Moreover, officials can also help a hand in popularizing mobile payment through facilitating this type of payment in different kinds of administrative procedures.

In Vietnam, mobile payment has tended to develop positively in recent years. More and more people are starting to use mobile payment apps. From the research results, the authors make some reference suggestions to improve the quality of mobile payment services in Vietnam and attract many new users, helping mobile payment service businesses expand domestic and international markets.

For official organisations such as the State Bank, the Ministry of Finance, the Ministry of Industry and Trade, and the Information and Communications Ministry,... it is necessary to study and propose policies and regulations related to mobile payment to strengthen management and protect the interests of users. Authorities should strengthen inspection, supervision, and handling of violations related to mobile payments such as illegal goods trading, money laundering, and fraud, to safeguard mobile payment providers' and users' cyber rights. In addition, strengthening the construction of payment infrastructure such as data centres, payment networks, and cybersecurity systems should also be focused on to generate a positive usage experience, which indirectly promotes the country's digital economy. In addition, raising people's awareness about mobile payment services also needs special attention.

For mobile payment providers, such businesses should invest and upgrade technical systems, ensuring users' safety and personal information security. Security technology for personal information and bank accounts such as data encryption, SSL, two-factor authentication, and fingerprint and face authentication will be integrated into mobile payment applications to ensure user security and safety. Moreover, mobile payment service providers also need to strengthen promotional activities to drive awareness of their services; expand cooperation between service providers to create new, and diversified products that meet market needs as well. Finally, mobile payment businesses should pay attention to quality assessment activities and take into account users' feedback to capture the needs and understand the desires of target customers. Especially when customers are undergraduate students, businesses should focus on offering convenient services and reasonable prices to increase competitive ability toward winning this target customer segment.

5.3. Limitations and future researches' proposals

Regarding research limitations, firstly, this research focuses mainly on factors affecting the decision to use mobile payment by students in the North. Hence, the overview of factors affecting the decision to use mobile payment of people nationwide, in general, was neglected. Secondly, some other important factors that influence the decision to use mobile payments such as Perceived Risk (PR), Effort Expectancy (EE), and Performance Expectancy (PE),... have not yet been considered in this study. In addition, the authors have only developed a simplified research model in this study. Although this does not lessen the research result's accuracy, the research has not achieved the desired thoroughness.

Further studies may apply previously used research models to evaluate users' decisions to use different types of mobile payments, thereby comparing differences in the importance of technological characteristics for different types of mobile payments. Moreover, it is also a good idea to research on other issues related to mobile payments, rather than focusing on the determinants of mobile payments usage. Studies on mobile payments have also been worldwide ubiquitous (Bauer, Reichardt, Barnes & Neumann, 2005; Ondrus & Pigneur, 2006) with factors influencing mobile payment decisions as one of the most popular research directions (Dalhberg et al., 2015). This, unfortunately, limits research on other issues of mobile payments and indirectly leads to undue limits on human knowledge.

Abstract

The study aims at identifying the factors that affect the decision to use Fintech for the purpose of managing personal finance. Data collection was conducted by surveying Vietnamese residents in 63 provinces and municipalities, which were divided into two groups: users (N=648) and non-users (N=333). Besides, the research model was designed mainly based on TAM and UTAUT2, with 18 hypotheses to be tested. After verifying the validity of the model by Confirmatory Factor Analysis (CFA), the authors derived the Structural Equation Model results by bootstrapping method. Specifically, Operational Risk, Observability, Hedonic Motivation were among the factors with strongest impact on the Decision to Use of both groups. However, while Social Influence showed remarkable influence in the user group, it was proved insignificant in the non-user group. From the aforementioned findings, recommendations were given for governors and Fintech providers. For the government, they should focus on enhancing the legal framework and promoting high-tech environment for Fintech to thrive in Vietnam. For Fintech companies, it is advisable that they ensure the security of their customers, create user-friendly interfaces, as well as improve the productivity of the Fintech applications.

Keywords: *Decision to use, Fintech, Personal finance, Vietnam*

1. Introduction

Although people's ability to create material wealth has increased significantly and reached unprecedented milestones in history, the ability to manage finances has not caught up with such a speed (Fogarty, 2012). In some cases, it can be observed that a lot of people

often fall into financial exhaustion and become hopeless when emergency situations happen, even though they have enough income and assets. Fintech was born as a “savior” to make financial management more effective.

According to Van Loo (2018), the use of Fintech in personal financial management can increase consumer benefits and reduce the likelihood of a financial crisis. In particular, benefits for individuals made by Fintech can be achieved by allowing them to control their finances in real time (Brainard, 2016). Many applications and services available on the market easily connect with consumers' financial tools to make simple and accurate spending and financial budgeting plans, thereby helping them have a more accurate perspective in spending and saving (Banks of International Settlements, 2018). These often break down into a lot of categories, including groceries, paying bills, and dining out, then the app will calculate how much you save. This overview provides consumers with detailed information about the main expenditures for a certain period of time, giving them a clearer and more accurate perspective in spending and saving decisions in personal financial management.

The benefits of Fintech have been proven clearly, but is Fintech really reliable in managing personal finances? Users may face a number of disadvantages in adopting Fintech products, including the risk of financial loss and privacy concerns (Liébana-Cabanillas et al., 2014). The decision to use Fintech services in financial management is influenced by the customer's perception of risk: Financial Risk, Legal Risk and Operational Risk have a significant influence on the decision to use (Tang et al., 2020). Using survey data collected from 244 Fintech users, Ryu (2018) has shown that regulatory risk has the most significant negative impact, while convenience had the most positive influence on the decision to use Fintech in personal financial management. Therefore, it is extremely important to investigate the factors affecting the decision to use Fintech in personal financial management.

Therefore, the study with the topic “*Determinants of Decision to Use Fintech for Managing Personal Finance in Vietnam*” was chosen by the research team. Theoretically, the study will systematize the theoretical basis, concepts related to personal finance, personal financial management and Fintech services and the factors affecting the decision to use Fintech in personal financial management. This study will also help to enrich the scholarly treasure of this subject for Vietnam. In practical terms, the results of the study will provide the advantages and disadvantages of Fintech, which determine the use of Fintech by individuals in financial management and serve as a basis for businesses and companies. Fintech service providers can optimize products, satisfy customer needs and contribute to the development of the economy in general.

2. Literature reviews and Theoretical frameworks

2.1. Literature reviews

Overseas research on Fintech adoption intention often focuses on the intention to use a particular Fintech product like the following studies: robo-advisor (Casaló et al., 2010; Belanche, 2019); online payment (Caldeira et al., 2021); digital banking (Marakarkandy, 2017) rather than Fintech in general. Their research models are based on TAM or UTAUT2,

which means they include Performance Expectation, Ease of Use, Facilitating Conditions will be considered key predictors. The benefit-risk framework is similarly popular (Ryu, 2018; Tang et al., 2020).

In Vietnam, most studies on the subject were carried out on a small sample size (which mainly consists of students between the age of 18 to 24), namely Nguyen Dang Tue (2020), Nguyen Vinh Khuong et al. (2022). The former uses UTAUT to determine the major obstacles preventing the continuation of Fintech payment services usage. The results indicate that Perceived Usefulness, Technical Concern, Social Influence, Perceived Information, Perceived Need of Minimalism all have profound influence on the continual use of Fintech payment services. Due to being one of the first studies on Fintech adoption in Vietnam, it's possible that other unique factors of Vietnam are not yet considered. The benefit-risk framework can be seen in the study of Nguyen Vinh Khuong et al. (2022), which includes the benefits (Perceived Benefit, Economic Benefit) and risks (Perceived, Financial, Legal, Security, Operational Risk). Social Influence is also cited as a key factor in Fintech adoption intention, due to the 4.0 industrial revolution.

In conclusion, while the potential of Fintech in personal finance management is undeniable, considering the number of studies on related subjects (payment, online banking, robo advisors), up to now there have been very few studies directly related to personal finance done in a developing country like Vietnam. There is not yet any thorough qualitative research to identify the potential factors unique to Vietnam and its condition. Additionally, the research population is often not diverse while also being limited in size and scale, affecting the ability to generalize the result.

2.2. Theoretical frameworks

Unified Theory of Acceptance and Use of Technology (UTAUT2)

The Theory of Acceptance and Use of Technology (UTAUT) proposed by Venkatesh et al. (2003) is considered the combination of other models on users' new technology adoption, including Technology Acceptance Model (TAM). UTAUT posits that Performance Expectancy, Effort Expectancy, Social Influence and Facilitating Conditions are determining factors and Gender, Age, Experience, Voluntariness of Use are moderators. Based on UTAUT, Venkatesh et al. (2012) developed UTAUT2, which further includes Hedonic Motivation, Price Value and Habit as factors, to explain users' behaviors toward technological products.

Benefit-Risk Framework

The benefit-risk framework is also used to explain users' intention to use Fintech. According to Peter and Tarpey (1975), users will consider the benefits and risks of a product before making decisions that will maximize the net benefit. Lee (2009) attempted to identify the factors affecting online banking acceptance by proposing a model based on TAM and Theory of Reasoned Action (TAM). Perceived risk was considered a multi-dimensional construct (including security, financial, social and operational risk) while perceived benefit was not.

3. Method

3.1. Research model and hypotheses

Chain of hypotheses H1 → H6: Perceived Efficiency, Ease of Use, Social Influence, Facilitating Conditions, Hedonic Motivation, Price Value positively affect the decision to use Fintech for managing personal finance in Vietnam.

Chain of hypotheses H7a → H7d: Financial Risk, Security Risk, Legal Risk, Operational Risk negatively affect the decision to use Fintech for managing personal finance in Vietnam.

Hypothesis H8: Relative Advantage positively affects the decision to use Fintech for managing personal finance in Vietnam.

Hypothesis H9: Observability positively affects the decision to use Fintech for managing personal finance in Vietnam.

Hypothesis H10a: Compatibility positively affects Perceived Efficiency.

Hypothesis H10b: Compatibility positively affects Ease of Use.

Hypothesis H10c: Compatibility positively affects the decision to use Fintech for managing personal finance in Vietnam.

Hypothesis H11a: Innovation positively affects Perceived Efficiency.

Hypothesis H11b: Innovation positively affects Ease of Use.

Hypothesis H11c: Innovation positively affects the decision to use Fintech for managing personal finance in Vietnam.

3.2. Data collection and analysis

Secondary data

We employed the secondary research method by using available documents, articles as well as domestic and foreign research related to this topic. Besides, databases were also taken from reliable websites such as World Bank, General Statistics Office, General Population Census, etc.

Primary data

Step 1: Design the questionnaires for the research

The research team built a questionnaire referenced from previous research documents. The final questionnaire consists of 3 distinct parts: general knowledge about Fintech, questions about demography and measurement related to the research model.

Step 2: Determine the sample size for the study

Sample size is determined by using the inverse square root method of Kock and Hadaya (2018) with a mean of 5%. As Huber et al (2008) suggested that if the path system is at least 0.1, the correlation between the two variables will have a significant impact on the model, so the desired minimum path system is defined as 0.1. The formula would be:

$$n_{min} = \left(\frac{2.486}{|0.1|} \right)^2 = 609.1024$$

Therefore, a minimum of 610 observations is needed for the research.

Step 3: Distribute the questionnaire to targets

As the survey's subjects were identified as individuals nationwide, the research team decided to expand the study participants to have the most comprehensive view of the use of Fintech in personal financial management in Vietnam. To conduct the research, the research team applied the convenience sampling method. From there, we asked people to spread the word and refer the questionnaire to others. In addition, the research team distributed the questionnaire to online public community groups to collect more answers. In total, 1017 valid research samples were collected.

Step 4: Data analysis

Data was updated into Excel to perform analysis of descriptive statistics and then transformed to SPSS 20 software and SmartPLS 4.0.8.2 software for measurement models as well as linear structural equations.

Proposed Model

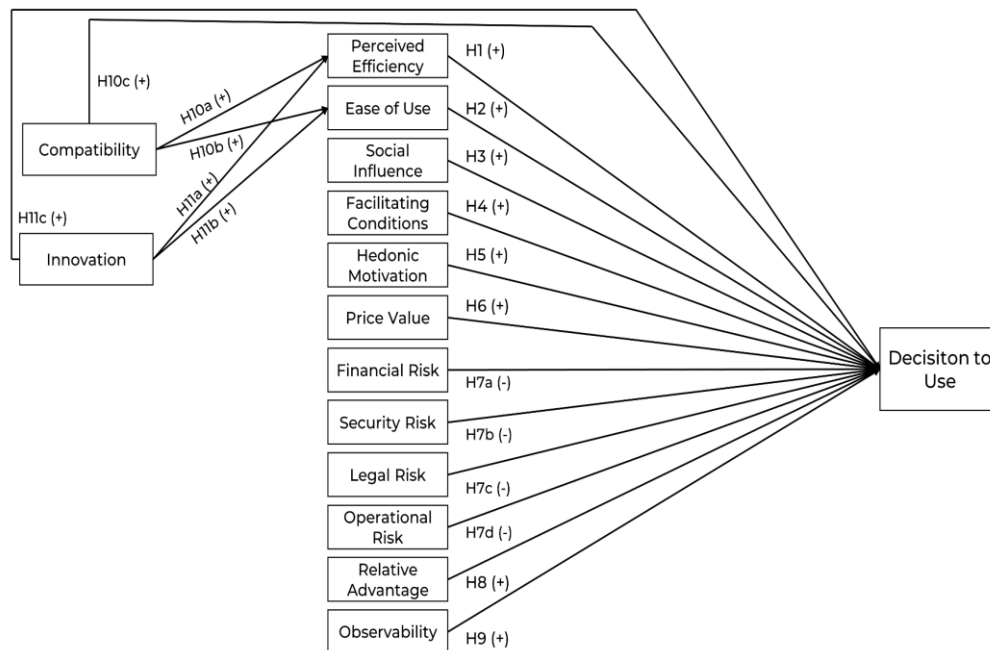

Figure 1. Proposed Hypothesis Model

3.3. Participants

The survey has received 1017 valid responses from residents across Vietnam. The descriptive statistics of the sample is listed in Table 1. The age group 18-25 accounted for the highest percentage (29.9%), and above half of the respondents belong to the younger part of the population (18-35). Regarding career, students and civil servants comprised the majority of the sample, with the proportion of 27.6% and 22.8%, respectively. Meanwhile,

the percentage of users doubled that of non-users, and the most popular family size was the nuclear family of 3-4 members. The two major monthly income groups were 10-20 million (31.3%) and below 5 million (24.9%).

Table 1. Demographic information of the sample

Characteristics		N	%	Characteristics		N	%
Gender	Male	603	59.3	Usage	Used	684	67.3
	Female	414	40.7		Not used	333	32.7
	Total	1017	100		Total	1017	100
Age	Below 18	90	8.8	Monthly income (million VND)	Below 5	253	24.9
	18 - below 25	304	29.9		5 - below 10	184	18.1
	25 - below 35	302	29.7		10 - below 20	318	31.3
	36 - below 50	274	26.9		20 - below 30	191	18.8
	Above 50	47	4.6		Above 30	71	7.0
	Total	1017	100		Total	1017	100
Career	Student	281	27.6	Family size			
	Civil servant	232	22.8		1 - 2 members	321	31.6
	Self-employed	154	15.1		3 - 4 members	481	47.3
	Finance	159	15.6		5 - 6 members	166	16.3
	IT	144	14.2		Above 7 members	49	4.8
	Pension	47	4.6		Total	1017	100
	Total	1017	100				

Source: Summary of the authors' results

4. Results

4.1. Confirmatory Factor Analysis (CFA)

Reliability: The assessment of Cronbach's Alpha showed that the model reached significantly high reliability (>0.8) for both groups. Additionally, Composite Reliability (CR) indices of the two groups exceeded 0.897, hence satisfying the threshold (>0.7) proposed by Nunnally and Bernstein (1994). Besides, Average Variance Extracted (AVE) results for two groups were higher than 0.688, which met the standard (>0.5). Therefore, all of the constructs were sufficiently reliable for the model.

Convergent validity: Considering outer loadings, the values for all independent variables satisfied the threshold of 0.708 (Hair et al., 2017). Next, AVE of every independent variable surpassed 0.5 in both groups, proving the convergent validity of the model.

Discriminant validity: All the constructs met the Fornell and Larcker (1981) standard when the AVE of one construct in the cross line exceeded every correlation

coefficient with other constructs in the same column. In addition, the highest HTMT ratio among the factors in the model was $0.697 < 0.9$, which achieved discriminant validity, according to Henseler et al. (2015). As a result, the proposed measurement model reached the discriminant validity.

4.2. Structural Equation Model (SEM)

The research employed the bootstrapping method with $N = 5000$ to measure the accuracy of the original path coefficient estimates (β). The results from bootstrapping would determine which observable variables were statistically significant in the model. Bootstrapping was conducted on the statistics of two groups: used and not used, then the results (shown in **Table 3**) would be used to analyze and compare between the two groups.

Table 3. The results for Structural Equation Model (SEM)

	Paths	Used (N=684)				Not used (N=333)			
		β	t-value	P-value	Results	β	t-value	P-value	Results

5. Discussion and Conclusion

5.1. Summary

Firstly, the group systematized the theoretical basis of the Unified Theory of Acceptance and Use of Technology (UTAUT2) and Benefit-Risk Framework, synthesizing relevant research papers related to the decision to use Fintech for managing personal finance.

Secondly, the group proposed a research model with 12 independent variables and 3 dependent variables.

Finally, based on the results from 1017 surveys, the group tested the significance of the factors affecting the decision to use Fintech for managing personal finance.

5.2. Discussion

The findings show that factors relating to risk have significant impact on the decision to use in both groups. Specifically, Operational Risk (OR) proves the greatest influence ($\beta = -0.345$) among the risks. This may be because Fintech remains fairly new in Vietnam, resulting in the doubt within users as to whether the Fintech applications are sufficiently well-built. Additionally, Financial Risk (FR) has the second highest impact on the decision of the non-users, yet slightly influences that of users. Ryu (2018) explained this result by arguing that the impact of financial risk may be demonstrated indirectly through other risks.

Hedonic Motivation (HM) and Observability (O) are the factors of major impact on the Fintech adoption for personal finance in both groups. For those who already used, observability ranked second in the impact ($\beta = 0.251$). This means that the practical experience of Fintech in managing personal finance of other people around them may promote their decision to use. For those who have not used, observability merely ranked fourth in impact ($\beta = 0.193$), lower than hedonic motivation ($\beta = 0.265$). It is predicted that the non-users are more concerned about their own enjoyment in using Fintech, rather than only observing that feeling in other people.

With regard to Perceived Expectation (PE), Innovation (I) positively contributes to the influence on this factor in both users and non-users, with path coefficients of 0.498 and 0.526, respectively. The implication is that Fintech products that can resolve the current difficulties in personal finance management can meet the expectation of the target customers. In the context of this research, the respondents mainly belong to the working age population, with 83.5%, and most come from families of 3-4 members. This demographic group tends to make the chief financial decision as they are the main financial supporter of the whole family. Indeed, some common mistakes in decision-making are unavoidable, for example, losing track of expenditures, having no saving plans or failing to identify investment risks (Nguyen Tien Thanh, 2020). For that reason, they are in need of an innovative solution to enhance their financial management skills. If Fintech providers are able to fulfill those requirements, they can gain higher satisfaction from current users, while promoting the motivation to access the products of potential customers.

The most distinguishable difference between the user and non-user group lies in Social Influence (SI), as this factor remarkably influences non-users, whereas shows hardly

any relevance in the decision of users. Perhaps people who have experience in using Fintech for their personal finance are not affected by others around them, since they have gathered enough knowledge and information about Fintech to reach their own decision. Meanwhile, non-users may be confused among different opinions about Fintech, as they lack the full awareness of the benefits brought about by Fintech. This finding resembles that of Lin et al. (2020) in investigating the adoption of mobile payment in Taiwan, at the time when this technology was not widely popular.

However, Ease of Use (EE) was reported with insignificant impact on the decision to adopt Fintech for personal finance in both research groups. This result contrasts various studies using the TAM model such as Kim et al. (2010), Kim et al. (2015), Chuang et al. (2016), Patel (2018), Nguyễn Vĩnh Khương et al. (2022). Taking the similar finding into consideration, Davis et al. (1989) explained that ease of use tended to show little influence in usage behaviors on the emergence of new technology as users still lacked a comprehensive experience of it. Therefore, Fintech providers should not direct their main focus on designing easy-to-use products at the market penetration stage in Vietnam.

5.3. Conclusions

As regards the group of people who have already used Fintech in financial management, based on 684 samples, Observability and Hedonic Motivation have the greatest positive influence on the decision to use Fintech, followed by Relative Advantage, Perceived Efficiency, Facilitating Conditions, Innovation, and Compatibility. On the contrary, the factors Ease of Use, Social Influence, and Price Value are sought to have no bearing on the Decision to Use. The relationship between Risk and Decision to Use is inverse with Operational Risk having the most detrimental effect, followed by Security Risk, Legal Risk, and Financial Risk. Two dependent variables Perceived Efficiency and Ease of Use are both affected by Innovation and Observability, these effects are in the same direction.

Among 333 samples for the Fintech non-user group, Hedonic Motivation and Social Influence most positively influence on Decision to use, followed by Observability, Facilitating Conditions and Compatibility. Ease of Use, Perceived Efficiency, Relative Advantage, Facilitating Conditions and Price Value are considered to have little significance to Decision to Use. The Decision to Use is adversely affected by Operational Risk, Security Risk, Legal Risk, and Financial Risk, with Operational Risk having the biggest impact. In terms of dependent variables, Efficiency Expectations, Innovation Motivation have a greater favorable impact than Observability. Observability, however, has a higher beneficial impact on the dependent variable Ease of use.

5.4. Recommendations

Recommendation for the Government

Firstly, the Government must first create a business environment with a clear legal framework to provide ease and fairness to competition. Objectives and regulations should support the interests of the Fintech sector while maintaining market integrity and

safeguarding consumers and investors. Managers and supervisors must behave in a neutral, zero-tolerance manner and keep a check for illicit activity. To prevent the exploitation of legal discrepancies, particularly in the setting of an expanding number of Fintech enterprises, monitoring and supervisory operations need to be intensified. The research team recommended that researchers and supervisors should create legislative laws after investigating and analyzing business desires so that the most relevant terms and conditions could be created in the circumstances.

Secondly, the Government must re-examine, alter, supplement, and adopt new policies as needed in order to create favorable conditions, encourage, and timely assist Fintech enterprises. The research team also suggests expanding on existing research and applying the “Regulator Sandbox” model for Fintech companies, which would allow them to experiment with new concepts and ideas in an environment free from contractionary regulations. Yet, the experiments continue to adhere to fundamental Fintech rules and guarantee customer security. Managers therefore will have a clear awareness of the feasibility of projects to make a decision regarding whether or not to alter current regulations.

Finally, the Government needs to upgrade the technology infrastructure to meet the requirements of high-tech development, especially security technology. User privacy and data security should be protected from cyberattack. Building a culture of trust with consumers about Fintech products and add-ons like personal financial management advisory services is also of primary concern. Users should be encouraged in accessing and using Fintech. In addition, the digitalization of personal identity or the integration of personal information into electronic devices need to be carefully examined. Steps involved in registering and using Fintech software must be publicly available via standardized guidelines to create the conditions for users to independently learn more about Fintech.

Recommendation for Fintech company

Firstly, Fintech companies must first enhance their technological infrastructure with a focus on user account security to gain customers' trust in utilizing fintech to manage their personal finances.

Secondly, to enhance productivity and operations, Fintech companies may consider utilizing state-of-the-art technologies. When users link their bank accounts with the application, for instance, eKYC (electronic Know Your Customer) technology can be used to identify clients electronically, verifying their accounts promptly and precisely in order to reduce the risk of confusion, data loss, or disclosure.

Thirdly, Fintech businesses that offer consulting and personal financial management services can collaborate with financial intermediaries (banks, financial companies, etc.) to build customer databases as well as transfer information between Fintech service providers and payment intermediates.

Lastly, the development of financial management application interfaces is also of importance where Fintech companies must place the emphasis on. These interfaces must be simple to use, have a clear design, stress brand recognition, and follow scientific layout principles.

Abstract

This study examines the impact of communicating with consumers through instant messaging on positive word-of-mouth using the SOR model. The study employs Cronbach's Alpha analysis, exploratory factor analysis (EFA), confirmatory factor analysis (CFA), and structural equation modeling (SEM) on 720 observations in Vietnam. The results show that the relationship between social perception, involvement, media richness, arousal, pleasure, and positive word-of-mouth all have a positive impact on each other. The study also indicates that social awareness has no significant influence on positive word-of-mouth. Based on the findings, the study provides suggestions for retail businesses today.

Keywords: *Mobile instant messaging (MIM), positive word-of-mouth (WOM), SOR model*

1. Introduction

Society is changing, which leads to some new trends in the process of goods from producers to consumers. In the past, consumers were marketed products through face-to-face interactions with salespeople, watching TV ads, or word-of-mouth among consumers. At the same time, sellers also found it very difficult to manage information and access buyers. However, today, everything has been improved on the digital platform and the Internet (Acai Sudirman, 2022). Therefore, consumer communication methods have also

differed significantly. The difference is reflected in the fact that many new forms of communication have emerged, such as personal communication (phone, instant messaging, email, etc.); social communication (based on the power of popular social media's spreading and interaction: Facebook, YouTube, LinkedIn, Blog, Forum, etc.) (Baran, Stanley J, 2021). Consumer communication has also taken new steps. This research focuses on the form of Mobile Instant Messaging (MIM).

As email marketing becomes more intrusive, social media advertising like Facebook and YouTube makes users lose interest, a different innovative solution is needed. With the "pop-up window" mechanism to display messages as soon as they are received, user-created lists can be seen by other users, which indicates when friends are online and ready to receive messages. They also can send and receive messages with images, text, video, location, voice messages, too (Delia Vazquez et al., 2017) ..., MIM stands out as a new and convenient way of communication that researchers have paid little attention to, although the level at which smart retailers can effectively communicate with consumers is very high (Delia Vazquez et al., 2017).

Recognizing the objective situation of society and the subjective nature of instant messaging on mobile phones - MIM, the student group has chosen the topic "The impact of communicating with consumers through instant messaging on positive word-of-mouth". From there, a solution is proposed to improve the communication activities of retail businesses today.

2. Literature review and Theoretical background

2.1. Literature review

Since its appearance, MIM has been a media revolution that is changing the way people communicate with each other (Sara H. Hsieh & Timmy H. Tseng, 2017). MIM applications have a strong impact, as they combine multiple services on one platform and allow users to update information in real-time, anywhere (Oghuma et al., 2015). Previous research on MIM has mainly focused on its benefits, functions, tasks, or social interaction (Sara H. Hsieh & Timmy H. Tseng, 2017). When studying the functionality of MIM, de Vos et al. (2004) showed the impact of usefulness on the application, how workers apply instant messaging in organizational situations (Isaacs et al., 2002), or how productivity loss can occur due to interruptions and distraction with MIM (Thatcher et al., 2008).

From the perspective of the benefits that MIM brings, Oghuma et al. (2015) developed a model to confirm the benefits of consumers to test the intention to continue using MIM of previous users. At the same time, research on the benefits of MIM for developing ELS has shown that MIM is a powerful educational tool because it encourages second language interaction among participants and has great potential to activate student participation (Alberto Andujar, 2015). Ying Tang & Khe Foon Hew (2017) studied the usefulness of MIM in education and showed that MIM improves learning by supplementing course content through dialogue activities and making social presence more easily developed through various computer-mediated communication channels (e.g., discussion forums). Daewon Kim (2018) concluded that the net welfare gain of texting via MIM exceeds the cost incurred when using it with LTE networks.

Starting from the social interaction aspect of MIM, Huang & Yen (2003) discussed how friends communicate to enhance their friendship; Sara H. Hsieh & Timmy H. Tseng (2017) also investigated the influence of emoticons and text messages on social interaction. In addition, some studies have examined consumer reactions to MIM. For instance, Deng et al. (2010) proposed that satisfaction and loyalty are influenced by trust and service quality; Gan (2017) analyzed the motivations driving the liking of MIM (WeChat) using the satisfaction theory; Zhang et al. (2017) examined the relationship between MIM (WeChat) social interaction and its impact on perceived value; Peng et al. (2016) investigated Chinese consumers' MIM conversion behavior, and specifically, Delia Vazquez et al. (2017) explored the environmental stimuli factors affecting emotions that then influence WOM activity.

Although previous studies have examined specific aspects of MIM usage and some studies have investigated the links between MIM and WOM, there has been no comprehensive study on the linkage between MIM and WOM. This study is conducted in the context of Vietnamese consumers and expands the survey sample. Additionally, it adds qualitative research. Building on previous studies, this study continues to address the relationship between social perception, media richness, involvement, arousal, and eWOM in the context of Vietnam. Furthermore, this study provides recommendations and solutions for retail businesses in Vietnam.

2.2. Theoretical Background

The environmental psychology theory proposes that stimulations from the environment are related to human behavioral and emotional responses (Mehrabian & Russell, 1974). Psychologists Mehrabian and Russell suggest that environmental stimuli (S) lead to emotional responses (O), which in turn drive consumer behavior (R), predicting the stimulus-organism-response (S-O-R) model. In the retail industry, Vieira (2013) used the S-O-R model to explain and present evidence of the relationship between various environmental cues and their impact on consumer responses. Li and Yeh (2009) studied the level of satisfaction, decision-making, trust, and positive responses of customers toward the e-commerce environment. Gan (2017) called for new approaches to enhance the current theoretical approach by integrating aspects of social influence theories. Wang and colleagues (2007) integrated the social response theory and S-O-R model, which creates a conceptual model to test the impact of web social cognition on pleasure and arousal. Building on the existing research, this study uses the S-O-R framework, combining social response theory and media richness theory, to clarify the impact and influence on consumer emotions.

Based on the theoretical framework, the following hypotheses are constructed and selected to fit the practical context of Vietnam:

Socialness Perception (XH)

Wang and colleagues (2007) argued that Socialness Perception directly and positively influences the emotions, behaviors, and actions of consumers. Social awareness is defined as the phenomenon in which humans perceive computerized machines as social agents (Reeves & Nass, 1996; Steuer & Nass, 1993). Short and colleagues (1976) stated that the

interaction between humans and computers is directly and positively affected by social consciousness, an individual's loyalty is improved through high-quality social interaction and social environment (Oliver, 1997).

H1: Socialness Perception has a positive impact on pleasure when using messenger.

H2: Socialness Perception has a positive impact on arousal in messenger.

H9: Socialness Perception has a positive impact on involvement in messenger.

H11: Socialness Perception has a positive impact on word-of-mouth communication in messenger.

Involvement (TG)

Involvement is a state that affects the goal aroused in the specific object that consumers are experiencing. Huang & Li (2013) argue that engagement reflects the level of consumer focus on the actions they are experiencing during use. Richins & Bloch (1986) assert that engagement is related to situational or long-term aspects. When consumers engage, they focus on the experience, chatting with friends, enjoying messages from the retailer's messenger or connecting with the retailer (Delia Vazquez et al., 2017). This focus leads to improved communication effectiveness and improved user experience (Huang & Li, 2013), positively affecting the emotions of users connected to each other during use. Individuals who are engaged in long-term shopping can directly experience the joy of exploring the shopping environment (Machleit & Eroglu, 2000; Wakefield & Baker, 1998). Studies show that high engagement leads to high emotional arousal and increases consumption experience (Wakefield & Blodgett, 1994). Engagement is stimulated by pleasure and interest when experiencing the online shopping environment. Therefore, the research team proposes the following hypotheses:

H3. Involvement has a positive effect on pleasure during the use of Messenger.

H4: Involvement has a positive effect on arousal during the use of Messenger.

Media Richness (DD)

Messenger has many practical and useful functions that are suitable for users, such as sending text, images, and text messages with multiple images, voice chat, news alerts, in-app shopping, collecting brand messages, alerting new music, and so on (Deng et al., 2010). Multimedia communication media have many benefits in transmitting more complex messages, thereby improving task performance (Pollach, 2008). Users focus more on the ability to disseminate and spread information on media than on the sender's emotional state (Pollach, 2008), and richer media communication leads to more positive emotional states when emotions and feelings can be shared in the process of information exchange (Pollach, 2008; Daft and Lengel, 1986; Daft et al., 1987; Lengel and Daft, 1989). Therefore, consumers using new multimedia mobile technology can enrich their mobile experience and improve their enjoyment and excitement in using it (Li et al., 2012; Davis, 2010). This leads to the following hypotheses:

H5: Media Richness has a positive effect on pleasure in using Messenger

H6: Media Richness has a positive effect on arousal in using Messenger

H10: Media Richness has a positive effect on involvement in using Messenger.

Pleasure (NV)

The SOR model of Mehrabian and Russell indicates that emotions are influenced by stimulating from the environment and impact of human behavior and decision-making (Russell and Mehrabian, 1977). Russell and Mehrabian (1977) developed the PAD emotional state model, which includes joy, arousal, and dominance. It has been applied many times in the context of consumer emotions. However, recent research by Koo, D. M., & Ju, S. H. (2010) on online retailing excludes the dominance aspect, as joy and arousal can capture the full range of appropriate emotions in consumer decision-making.

H7: Pleasure has a positive effect on positive WOM

Arousal (KT)

Recent studies have also demonstrated and tested the positive relationship between emotion and behavioral intention (Lin & Liang, 2011). Arousal is the personal feeling of excitement, motivation, and enthusiasm when shopping online (Koo, D. M., & Ju, S. H. (2010)). Experimental studies have also provided arguments to verify the positive relationship between emotion (joy, arousal) in mobile commerce and consumer behavioral intention (positive WOM) (Deak, 2011; Thuy, 2019). This leads to the following hypotheses:

H8: Arousal has a positive effect on positive WOM

H13: Arousal has a positive effect on Involvement

After adjusting for preliminary research feedback in real conditions in Vietnam, the proposed research model by the research group is as follows:

Figure 1. Proposed research model

Source: Compiled by the research team.

3. Method

3.1. Data Collection

Primary data is collected through online and offline surveys from consumers who use Facebook in Vietnam and have purchased from retailers through this channel.

Secondary data is collected from articles, relevant studies, as well as from the General Statistics Office of Vietnam, the Telecommunications Bureau of the Ministry of Information and Communications of Vietnam, and the White Book of E-commerce in Vietnam.

3.2. Scale Development

The variables used in this study include Socialness Perception, Involvement based on Zaichkowsky's (1985) study, Media Richness based on Daft and Lengel's (1986) study, Pleasure based on Raghunathan and Irwin's (2001) study, Arousal based on Mehrabian and Russell's (1974) study, and WOM based on Maxham and Netemeyer's (2002a, 2002b, 2003) and Delia Vazquez et al.'s (2017) studies. The study also discusses moderating variables such as Gender, Age, Shopping Field, and Income.

All measurement scales were based on previous English-language studies, and the authors of this study performed back-translation to ensure equivalence. The authors also discussed and adjusted the measurement scales to ensure clarity and suitability for the research context in Vietnam. A preliminary study is conducted with 10 consumers, and adjustments are made to ensure the logic and understandability of the survey questionnaire.

3.3. Data processing

For primary data: The authors select and filter the answers from the questionnaire table. Invalid answers such as selecting a missing answer or respondents who do not belong to the research group are removed. Information in the questionnaire table is encoded for convenient data processing, for example, 'Male' is assigned as 0, and 'Female' is assigned as 1. Questions about cognition are measured on a 5-point Likert scale, with scores ranging from 1 - Strongly Disagree, 2 - Disagree, 3 - Neutral, 4 - Agree, 5 - Strongly Agree. Then, the data is entered into the SPSS version 20.0 and AMOS version 20.0 software in the following sequence: (1) Descriptive statistics of the observed sample, (2) Reliability testing with Cronbach's Alpha; (3) Exploratory Factor Analysis (EFA); (4) Confirmatory Factor Analysis (CFA); (5) Structural Equation Modeling (SEM) analysis.

4. Results and discussion

4.1. Research findings

4.1.1. Descriptive statistics

Table 1. Descriptive statistics results.

Quota	Amount	Proportion (%)
Gender		
Male	181	25.14
Female	539	74.86
Age range		
Under 20 years old	137	19.03
20 - 40 years old	472	65.56
40 - 60 years old	99	13.75
over 60 years old	12	1.66
Education		
Under college	185	25.7
University	498	69.16
Postgraduate	37	5.14

Source: Compiled by the research team.

4.1.2. Reliability testing of the scales

After conducting Cronbach's Alpha analysis for the scales, the results showed that the social perception, involvement, media richness, pleasure, arousal, and positive word-of-mouth scales had Cronbach's Alpha coefficients of 0.916, 0.876, 0.902, 0.896, 0.883, and 0.856, respectively. All of them indicate good scales because they are greater than 0.8 (Nawai et al., 2020). The inter-item correlation coefficients for the total variables were all greater than 0.3. Therefore, the scales were used in the subsequent analysis.

Table 2. Results of reliability testing of the scales.

No.	Names	Number of items	Cronbach's Alpha
1	Socialness Perception	3	0.916
2	Involvement	4	0.876
3	Media Richness	3	0.902
4	Pleasure	4	0.896
5	Arousal	4	0.883
6	Positive WOM	3	0.856

Source: Compiled from SPSS 20.0

4.1.3. Exploratory factor analysis (EFA)

The Kaiser-Meyer-Olkin (KMO) measure is 0.941, greater than 0.5, and $p = 0.001 < 0.005$, indicating high significance. All 26 observed variables is extracted into 6 factors with eigenvalues greater than 1. The total extracted variance is 73.435%, which exceeds the threshold of 50%. The factor loadings of all variables is greater than 0.5 and suitable to continue with confirmatory factor analysis (CFA) to ensure the quality of the scales before testing hypotheses in subsequent steps.

Table 3. Results of Exploratory Factor Analysis

KMO and Bartlett's Test		
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.941
Bartlett's Test of Sphericity	Approx. Chi-Square	12984.036
	df	325
	Sig.	.000

Source: Compiled from SPSS 20.0

4.1.4. Confirmatory factor analysis (CFA)

After conducting EFA to determine the appropriate observed variables, the study proceeds with CFA to evaluate the quality of the scales before testing the proposed hypotheses. CFA is used to test the unidimensionality, convergence validity, and discriminant validity of the variables using AMOS 20 software. The results indicates a good model fit, and all values meet the required criteria. The results is accepted from good to very good.

Table 4. Results of Parameters Testing the Appropriateness of the Research Model

Measure	Estimate	Interpretation
CMIN	756,095	
df	284	
CMIN/df	2.662	
GFI	0.925	Good
CFI	0.963	Very good
TLI	0.958	Good
RMSEA	0.048	Good
PCLOSE	0.771	Good

Source: Compiled from AMOS

4.1.5. Structural Equation Modeling (SEM) analysis

After conducting the confirmatory factor analysis (CFA) to assess the quality of the measurement scale, the study proceeds to SEM analysis to test the hypotheses. $CMIN/df = 2.676 < 3$, $GFI = 0.924 > 0.9$, $CFI = 0.964 > 0.9$, $TLI = 0.958 > 0.9$, $RMSEA = 0.048 < 0.08$, $PCLOSE = 0.748 > 0.05$. These results indicate that the model fits the evaluation data of Hu & Bentler (1999). The study used second-order factors of the SEM model to fit the proposed

hypotheses. According to J. Wang & Wang (2019), using second-order factors contributes to the variation between first-order factors.

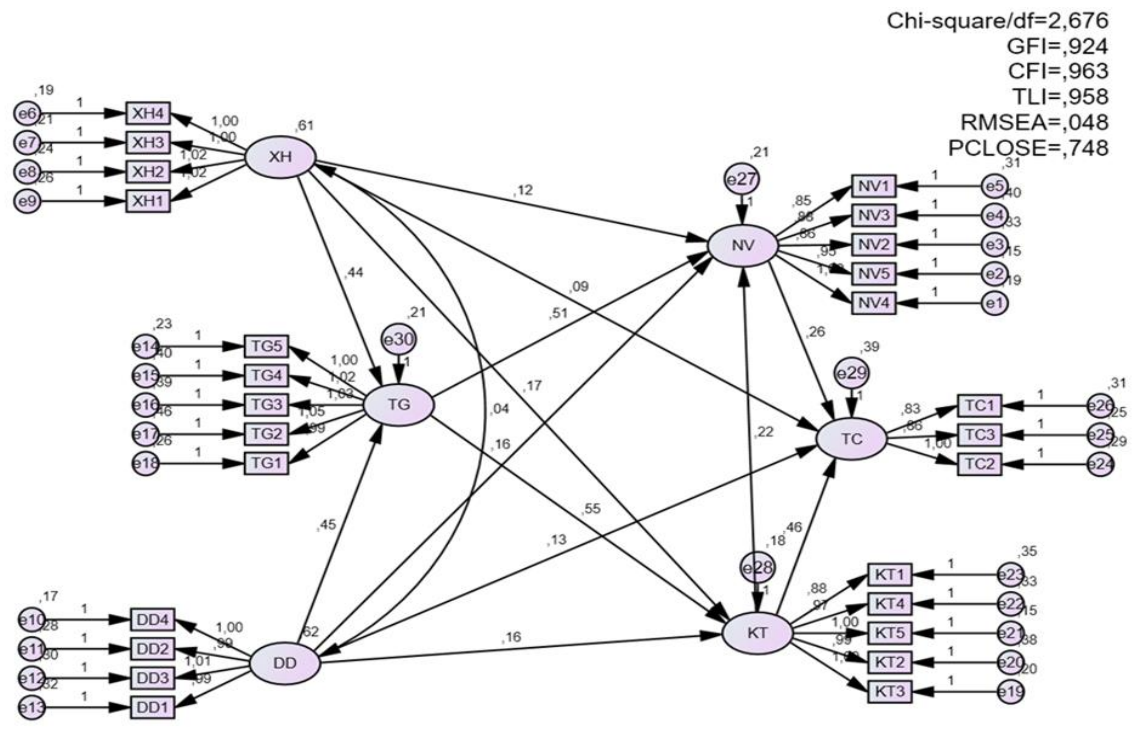

Figure 2. SEM model structure

Source: Compiled from AMOS

Table 5. Results of structural model analysis

TC	<---	KT	,460	,368	,072	6,396	***

Source: Compiled from AMOS

From the results above, it can be seen that out of the 13 initial hypotheses proposed, 12 hypotheses are accepted and all have a positive impact. Only one hypothesis was rejected at a 95% significance level, which is the perception of social influence on positive word-of-mouth.

4.2. Discussion of research results

The study reveals the relationship between Socialness Perception, involvement, media richness, Involvement, and Arousal towards positive word-of-mouth through the use of Messenger. The hypothesis of Socialness Perception do not have a direct impact on positive word-of-mouth but rather indirectly through involvement, pleasure, and arousal. The findings show that in today's context, consumers are stimulated when retailers apply communication tools to consumers through instant messaging on mobile phones. This stimulation has led consumers to feel more stimulated than introducing products through direct retail. This result was contrary to Delia Vazquez and colleagues (2017). The differences in research results may be influenced by the differences in culture between Chinese and Vietnamese consumers. The impact of media richness was also broader than the studies of Delia Vazquez and colleagues (2017) and Brunelle (2009), where media richness had an impact on all aspects except social cognition. It can be seen that businesses today have effectively applied multimedia communication channels to consumers with diverse communication channels in exchanging information or expressing emotions.

5. Conclusion and recommendations

5.1. Conclusion

Thanks to its superior characteristics, instant messaging via mobile phones opens up a golden opportunity for retailers today. This communication platform helps businesses reach their target customers conveniently. When customers feel comfortable contacting the business, loyalty and satisfaction will increase.

Further research can expand the observation sample by approaching male consumers and surveying more industries. It is interesting that the research also shows that gender, age, and education level also affect positive word-of-mouth. However, the study still has some limitations, such as not specifying how consumers spread word-of-mouth. The sample size of the study is not large enough to have a high representative value, and cultural differences between countries have not been studied.

5.2. Recommendations

First, retailers should have a multi-channel, multimedia marketing strategy and maximize the advantages of the richness of Vietnam's current media. This approach has a positive impact on positive WOM, thereby helping retailers build brands and stimulate consumers to have positive behaviors and emotions towards products and retail brands. In addition to traditional methods, retailers should approach new social networks like Tiktok, Instagram; advertise their products on e-commerce platforms; approach other smart electronic devices that can link users with smartphones like smart watches (Iwatch), intelligent robots, etc. and keep up with the pace of development of the era by using AI - Chat GPT is an example.

Second, customer experience needs to be improved and focused on more. Retailers should build an appropriate approach to reach consumers, stimulate their participation in the communication process with the retailer. Research has shown that engagement has a positive impact on happiness and stimulation. This is also the process that helps retailers understand the "insights" as well as the needs of consumers. This also requires the attitude of salespeople at retail stores.

Third, enhance the social awareness of consumers, retailers, and the government. This policy suggestion requires support from all three parties: consumers need to be mindful and cautious when researching and purchasing products, avoiding unverified information and scams; retailers need to be honest and transparent in marketing their products, building an ecosystem and guiding consumers; the government and regulatory agencies need to enact specific consumer protection policies such as reviewing laws in the Consumer Protection Act, closely monitoring the business activities of retailers, and supplementing communication channels with consumers to promptly address and support consumer reports.

Fourth, retailers need to increase conversion rates by promoting their sales platforms. When content is invested in and shared on social media pages, it not only helps improve trust and credibility with existing customers but also attracts new customers interested in the product. At this point, social media helps businesses naturally increase conversion rates, directly impacting the revenue of retailers. This suggestion emphasizes marketing strategies, marketing executives, and the quality marketing rate, from the bidding process to buying and delivering products to consumers without many obstacles or returns,... This raises questions about the method and dedication of retailers when inviting consumers.

Abstract

The digital era has created favorable conditions and opportunities for businesses to leverage emerging technologies to enhance the quality of their products and services. AI technology, in particular, plays a critical role in marketing activities for payment intermediaries, such as e-wallet service providers. This paper aims to investigate the influence of AI marketing on Hanoi university students' love for e-wallet brands. Base on the sample of 641 surveys collected by structured questionnaires, findings from the study reveals that: (i) The current chatbot systems used by e-wallets do not provide the same level of smoothness as person-to-person consultations; (ii) Interactive personalization has the greatest impact on user experience; and (iii) Passive digital footprints have not yet had a significant enough impact on brand love. The authors have expanded on previous studies by introducing four new factors in AI Marketing: information personalization, interactive personalization, active digital footprint and passive digital footprint. The study provides several recommendations to assist e-wallet businesses in their digital transformation processes, specifically regarding the application of AI marketing to enhance brand love among Hanoi University students.

Keywords: *AI Marketing, brand love, e-wallet, user experience*

1. Introduction

In January 2021, the Vietnamese government introduced a national strategy aimed at promoting research, development, and application of AI technology until 2030. The goal is to make Vietnam a leading country in AI research, development, and application within ASEAN and globally. By 2025, Vietnam aims to be among the top 5 countries in ASEAN

and the top 60 countries in the world for AI. The government's initiative has led to increased interest in the application of AI in various fields, including marketing. There are currently around 40 e-wallets operating in the Vietnamese market, with five popular e-wallet brands among social media users. Along with the development of the economy, non-cash payments, including e-wallets, are becoming an inevitable trend among young people, who represent a potentially profitable user group. E-wallet brands in Vietnam are using AI marketing to reach users at touchpoints, improve their experience, and foster brand love. However, the number of studies on the impact of AI on user experience and brand love, specifically for e-wallet brands in Vietnam, is limited. Therefore, this article will focus on addressing this research gap.

College students share common features including favoriting, understanding, and easily accepting new technologies. According to the statistics from the Ministry of Education and Training (2020), Vietnam has 1,672,881 students attending public and non-public universities in total. It can be seen that students play an important role and are the audience with great potential for exploitation in the total number of e-wallet users in the Vietnam market.

For the above reasons, the study of "*The Impact of AI Marketing on Brand Love among Hanoi University Students: The Case of E-wallets*" is conducted by the authors to clarify the factors of AI Marketing which are currently being applied by e-wallet brands and their level of influence on user experience and brand love.

This article is structured into five parts: (i) Introduction; (ii) Literature Reviews and Theoretical Basis, (iii) Research methodology; (iv) Results, and; (v) Discussion and Conclusion.

2. Literature Review and Theoretical Basis

2.1. Literature Review

AI is defined as an "intelligent computing agent" (Poole & Mackworth, 2010). In other words, the definition reflects the idea that AI systems are not merely passive tools but rather active agents that can act autonomously and intelligently to achieve specific objectives. This definition differs from previous notions that restricted AI to machines programmed by algorithm, lacking independence. Regarding AI Marketing, the definition refers to the developing artificial intelligent system that uses information about customers, competitors, and industry leaders to suggest and implement marketing strategies that generate the best results. (Overgoor et al., 2019).

E-wallets are widely regarded as a secure and user-friendly payment option, particularly in light of ongoing technological advancements, suitable for all types of users (Dang et al., 2021). According to the Circular guiding the intermediary payment services of the State Bank: "*E-wallet service*" is a service that provides users with an electronic identity account created by service providers on the carrier. information (such as electronic chips, mobile phone sims, computers, etc.), allowing a monetary value to be stored and used as a means of non-cash payment."

According to Robert (2005), brand love represents the most robust emotional connection between a brand and its users. Users often express their love for a brand through

expressions, such as “I like this car” or “I love shopping here”. Despite facing a plethora of options, users only develop a strong affinity towards a select few brands, particularly those that foster a loving relationship with a brand love-centric (Ahuvia, 2005).

2.2. Research hypothesis

2.2.1. AI Marketing efforts in e-wallet experience

Kotler (2021) has identified five essential pillars of Digital Marketing 5.0, including Predictive Marketing, Contextual Marketing, and Augmented Marketing. In this study, the authors investigated the current applications of AI Marketing in e-wallets, comparing them with the components of Digital Marketing 5.0, and deduced the various applications of AI Marketing in the e-wallet user experience. The selected applications share a common characteristic which is that they are visible and can be perceived by e-wallets’ users, which are: (1) Intelligent Interaction, which corresponds to the augmented marketing platform; (2) Personalization, which corresponds to the contextual marketing platform in the digital era; and (3) Digital Footprint, which corresponds to the predictive marketing platform.

In the e-payment industry, the development of human-imitation technologies is still limited, with chatbots powered by AI being the primary form. Therefore, the authors focused on investigating chatbots to represent the intelligent interaction variables, considering the three crucial factors from DeLone and McLeans’s IS Success Model: information quality, system quality, and service quality. *From there, the authors hypothesized [H1]: Intelligent interaction has an impact on user experience.*

According to Darshana Desai (2021), AI-integrated personalization is a strategy businesses use to address potential customer needs and increase profits by providing the right information at the right time through the right channels. Personalization is a key high-tech element of context marketing, as described by Kotler (2021) in Marketing 5.0. It operates based on the user's intention and prior behavior, which led the authors to employ scales from the UTAUT model to measure the impact of personalization on the e-wallet user experience. *From there, the authors proposed the following hypothesis [H2]: Personalization has an impact on user experience.*

Digital footprint plays an important role in marketing. Specifically in re-marketing, Arya et al. (2019) have demonstrated, this digital trace is especially important in helping marketers understand the needs, habits, and behaviors of users. Since digital footprint is an aspect of AI Marketing in digital platforms using context which has many similarities in the attitudes and satisfaction levels of e-wallet users, therefore, the authors used the U&G Model (Uses and Gratification Theory) to measure digital footprint variables. *From there, the authors proposed the following hypothesis [H3]: Digital footprint has an impact on user experience.*

2.2.2. User experience

User experience has been recognized as a critical component of contemporary marketing. Previous research has highlighted that user experience involves the interaction between users and brands which has a lasting impact on the user's perception. User experience

has been proven to be influenced by three AI Marketing factors: Intelligent Interaction, Personalization, and Digital Footprint. Therefore, the authors concentrated on investigating the user experience based on the influence of each of these factors. *From there, the authors proposed the following hypothesis [H4]: User experience has an impact on brand love.*

2.2.3. Brand love

The authors has incorporated the variable "brand love" into their model to propose a viable solution based on the impact of AI marketing applications on user experience, specifically the unique relationship between brands and users when they interact with AI marketing features such as intelligent interaction, personalization, and digital footprint within their e-wallet experience.

2.3. Framework

With the above analysis, the authors selected and developed the research model as shown in the figure below. Which, the attached hypotheses have been stated related to each factor:

Figure 1. Proposed research model

3. Method

3.1. Research sample

To collect data for the study, the authors conducted a survey of university students who are currently studying and living in Hanoi City. The survey utilized a combination of factor analysis and linear regression, with a model that comprised 37 measurement variables. In total, 686 students were surveyed, and valid responses were obtained from 641 participants, which indicates a reliable sample size.

With 641 valid responses that the authors received, there were more women than men among the study participations. The proportion of women accounted for 63.5% while the number of men accounted for only 36.5%. This may signify that women are more open to discuss their experience using e-wallets. The majority of the respondents were second-year students, comprising 59.3% of the sample. More than 70% of the participants reported having an average monthly income of less than 3 million VND, with the remainder earning

3 million VND or more per month. These demographic characteristics provide insights into the sample of students surveyed and may influence the results of the study.

3.2. Scale

The observed variables were measured using a 5-point Likert scale, ranging from 1 (Strongly disagree) to 5 (Strongly agree), and were based on established models from previous research by foreign authors, including the Information System Success Model (Delone & McLean, 2003), the Theory of Acceptance and Use of Technology (Venkatesh et al., 2003), and the Use and Satisfaction Model (U&G Model) developed by Xueming Luo (2002).

4. Results

4.1. Testing reliability using Cronbach's Alpha

The analysis results showed that Cronbach's Alpha coefficients of all scales were greater than 0.6. The observed variables all had total intercorrelations greater than 0.3 and all were smaller than the common Cronbach's Alpha value. The final results obtained showed that the scales' values for each factor group were all reliable and the data correlations were consistent with the constructed scales.

Table 1. Results of the reliability test of the measurement scale

Factor	Cronbach's Alpha	Total Variance Explained	Number of Items
Intelligent Interaction (CB)	0,932	0,731 - 0,776	0/9
Personalization (PN)	0,912	0,561 - 0,723	0/12
Digital Footprint (FOOT)	0,842	0,391 - 0,657	0/9
User experience (CX)	0,843	0,677 - 0,731	0/3
Brand love (BL)	0,861	0,692 - 0,742	0/4

Source: Author's team processing survey data (2023)

4.2. Exploratory Factor Analysis - EFA

The results of the EFA analysis for all factor groups showed significant correlations ($\text{sig} = 0.000 < 0.05$) among variables in the overall sample, with a KMO coefficient of 0.941 ($10.5 < \text{KMO} < 1$) and an eigenvalue extraction coefficient of 1.145, indicating the suitability of the EFA analysis. However, the factor loadings of the observed variables PNa2, PNb3, and FOOTb2 did not meet the requirements, so the group excluded these observed variables and proceeded to perform a second EFA analysis.

Table 2. KMO and Bartlett's Test results of independent variables for the second time

Kaiser-Meyer-Olkin	0,941
Bartlett's test	11474,668
Df	351
Sig.	0,000

Source: Author's team processing survey data (2023)

The KMO test result for the second analysis was 0.941, which is greater than 0.5. Therefore, the research group initially concluded that these factors were entirely appropriate for the study dataset. The result of Bartlett's test was 11474.668 with sig = 0.000, confirming that the observed variables were correlated with each other and the factor analysis process with the data was reasonable. The total variance extracted from the independent variables was 68.489% (>50%), indicating that the research model was suitable for the EFA test.

Table 3. Results of Second Rotation Matrix

	Factor				
	1	2	3	4	5
CBa1	0.711				
CBa2	0.741				
CBa3	0.713				
CBb1	0.731				
CBb2	0.742				
CBb3	0.735				
CBc1	0.711				
CBc2	0.759				
CBc3	0.749				
PNa1				0.733	
PNa3				0.573	
PNb1				0.761	
PNb2				0.803	
PNc1			0.686		
PNc2			0.802		
PNc2			0.763		
PNd1			0.595		
PNd2			0.622		
PNd3			0.582		
FOOTa1		0.833			
FOOTa2		0.864			
FOOTa3		0.876			
FOOTb1		0.639			
FOOTb3		0.606			
FOOTc1					0.843
FOOTc2					0.872
FOOTc3					0.854

Source: Author's team processing survey data (2023)

The factor loadings were all greater than 0.5, and no variables loaded on both factors with similar loadings. Therefore, the factors were reliable and distinct in the exploratory factor analysis. However, according to the rotated factor matrix, two-factor groups, PN and FOOT, were each split into two new factor groups. Based on the theoretical foundation and content of the observed variables in the PN factor, the authors agreed to name the first new group Interactive Personalization (PNIT) and the second new group Informative Personalization (PNIF). For the FOOT factor, the first new group was named Active Digital Footprint (AFOOT) and the second new group was named Passive Digital Footprint (PFOOT).

The separation of the "Personalization" factor into two sub-factors can be explained by its dependence on the relationship with the user, based on the 3 levels of personalization in marketing (Kotler, 2021). At level 1, personalization of information is a low level of personalization, where marketing activities rely on information collected from users by businesses. This includes providing suitable proposals such as advertising messages, product selection, promotions, etc. Level 2 is interactive personalization, where marketing activities reach users through interactive experiences with e-wallets. At this level, marketers create a two-way communication interface and interact intelligently with users

The separation of the "Digital Footprint" factor can be explained by differences in users' perceptions of how businesses approach them. If users actively leave a trace, they tend to feel satisfied when receiving relevant recommendations. Conversely, it may cause discomfort if users are not willing to share information. This supports the findings of Arakemath's (2015) research, where the Digital Footprint was classified into two groups: Active Digital Footprint and Passive Digital Footprint.

After conducting EFA factor analysis, the original 30 observed variables were reduced to 27 variables and were subsequently divided into 5 factors, which were named as follows:

Table 4. Newly formed factors

Factor	Item Loadings
Intelligent interaction (CB)	CBa1, CBa2, CBa3, CBb1, CBb2, CBb3, CBc1, CBc2, CBc3
Interactive Personalization (PNIT)	PNa1, PNa3, PNb1, PNb2
Information Personalization (PNIF)	PNc1, PNc2, PNc3, PNd1, PNd2, PNd3
Active Digital Footprint (AFOOT)	FOOTa1, FOOTa2, FOOTa3, FOOTb1, FOOTb3
Passive Digital Footprint (PFOOT)	FOOTc1, FOOTc2, FOOTc3

Source: Author's team processing survey data (2023)

The splitting of PN and FOOT into 2 new variables led to the division of hypothesis H2 and hypothesis H3 into 4 new hypotheses: H2.1, H2.2, H3.1, and H3.2, as follows:

H2.1: Interactive personalization has an impact on user experience.

H2.2: Informative personalization has an impact on user experience.

H3.1: Active digital footprint has an impact on user experience.

H3.2: Passive digital footprint has an impact on user experience

4.3. Linear Regression Analysis

4.3.1. The Influence of AI Marketing on User Experience

The R2 (R-Square) coefficient is 0.594 > 0.5 - meaning that the control and independent variables explain 59.4% of the variation in the dependent variable. The Durbin-Watson (DW) statistic serves to test for first-order autocorrelation. According to Yahua Qiao (2011), if the DW value falls between 1.5 and 2.5, no autocorrelation is present. From the table, we obtain a Durbin-Watson value of 1.850, which meets the required value.

ANOVA table with sig. = 0.000 < 0.05 implies that the linear regression model constructed is appropriate for the population. The Sig. values of the t-test for the variables "Intelligent Interaction", "Interactive personalization", "Informative personalization", and "Active Digital Footprint" are all less than 0.05. Therefore, these variables all have significant explanatory power for the dependent variable "User experience". On the other hand, the variable "Passive Digital Footprint" has a sig. value > 0.05, indicating that it is not statistically significant and cannot explain the dependent variable "user experience" in this research model.

Table 5. Results of Regression Coefficient Analysis

Coefficients ^a								
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		B	Std. Error	Beta			Tolerance	VIF
1	(Constant)	0,382	0,122		3,142	0,002		
	CB	0,128	0,041	0,123	3,165	0,002	0,421	2,376
	PNIT	0,454	0,037	0,447	12,263	0,000	0,480	2,084
	PNIF	0,170	0,035	0,179	4,777	0,000	0,453	2,206
	AFOOT	0,147	0,026	0,179	5,624	0,000	0,634	1,578
	PFOOT	0,017	0,021	0,022	0,838	0,402	0,910	1,099

Source: Author's team processing survey data (2023)

Furthermore, the variable "Interactive Personalization" has the highest β coefficient. It can be observed that this factor has a significant impact on the dependent variable 'user experience' compared to the other factors. Next, the Variance Inflation Factor (VIF) is examined to check for multicollinearity. According to the Coe table, the VIF scores for all 5 factors are < 10, indicating that there is no multicollinearity among the independent variables. The regression model is presented below as a sample:

$$CX = 0,123*CB + 0,447*PNIT + 0,179*PNIF + 0,179*AFOOT$$

4.3.2. The impact of user experience on brand love

The Model Summary table shows that the R-Square coefficient is 0.491, indicating that the control and independent variables explain 49.1% of the variance in the dependent variable, while the remaining 50.9% is due to external factors and random error. The Durbin-Watson (DW) statistic is used to test for first-order autocorrelation. According to Yahua Qiao (2011), if the DW value falls between 1.5 and 2.5, there is no first-order autocorrelation. The table shows that the Durbin-Watson value is 1.974, which meets the required value.

Upon examining the ANOVA table, it was observed that the F-value for the hypothesis test of the model's overall fit to the population was [insert value] with a significance level of 0.000, which is less than the conventional threshold of 0.05. This implies that the linear regression model developed is appropriate for the population.

Table 6. Results of Regression Coefficient Analysis

Coefficients								
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		B	Std. Error	Beta			Tolerance	VIF
1	(Constant)	0,516	0,127		4,079	0,000		
	CB	0,800	0,032	0,701	24,817	0,000	1,000	1,000

Source: Author's team processing survey data (2023)

The significance value (Sig.) of the t-test for the "User experience" variable is less than 0.05. Therefore, all variables have significant explanatory power for the dependent variable "Brand love."

The VIF values were then examined to detect the presence of multicollinearity among the independent variables. As shown in the Coe table, the VIF value for the "User experience" variable is $1 < 10$, indicating that multicollinearity is not an issue. The regression model used in the study is presented below: $BL = 0,701 * CX$

4.4. Descriptive statistics of the impact of AI Marketing on brand love

Table 7. Descriptive statistics of factors

Factor	Observed variable	Standard deviation	Mean value (\bar{x})	
Intelligent interaction	The question-and-answer system of the e-wallet is easy to use	0,909	3,88	3,76
	The question-and-answer system of the e-wallet operates smoothly	0,919	3,74	
	The question-and-answer system of the e-wallet is reliable	0,895	3,78	

Factor	Observed variable	Standard deviation	Mean value (\bar{x})
	The question-and-answer system of the e-wallet provides timely information	0,894	3,75
	The question-and-answer system of the e-wallet provides accurate information	0,872	3,86
	The question-and-answer system of the e-wallet provides comprehensive information.	0,887	3,80
	The question-answering system of the e-wallet understands my inquiries accurately	0,915	3,63
	The question-answering system of the e-wallet meets my requirements quickly	0,912	3,69
	The question-answering system of the e-wallet provides useful solutions	0,904	3,68
Interactive personalization	I save time when using e-wallet for payment services	0,892	4,12
	I rarely make mistakes in transferring money when using e-wallet to make familiar payments	0,927	3,98
	I find it easy to operate when using an e-wallet	0,864	4,14
	I can easily make payments for familiar services using an e-wallet	0,865	4,16
Informative personalization	I use an e-wallet because many people around me use it	1,060	3,64
	I use an e-wallet because people around me have had good experiences and recommended it to me	1,081	3,53
	People around me believe that I should take advantage of personalized offers from my e-wallet	1,068	3,49
	The new and creative interface provides me with entertainment while using an e-wallet	0,932	3,79
	The suggestions and recommendations from my e-wallet provide me with interesting experiences	0,931	3,66

Factor	Observed variable	Standard deviation	Mean value (\bar{x})	
	I enjoy the reward point experiences when using an e-wallet	0,958	3,74	
Active digital footprint	I am comfortable when encountering e-wallet advertisements on the internet	1,109	3,11	3,06
	I am excited when e-wallet advertisements unexpectedly appear on my electronic devices	1,121	2,81	
	I find it exciting when e-wallet advertisements pop up unexpectedly on various platforms, such as Facebook, Google, Zalo, etc..	1,155	2,79	
	I believe the information from the e-wallet advertisements that I am using is useful	1,029	3,42	
	I rarely miss out on lucrative promotions from my e-wallet	1,125	3,21	
User experience	I am satisfied with my experience using an e-wallet	0,841	3,95	3,85
	The e-wallet provides all the features I need	0,867	3,88	
	The e-wallet meets my needs before I realize them	0,886	3,73	
Brand love	I enjoy using an e-wallet	0,922	3,84	3,60
	An e-wallet is my first choice when I use payment and money transfer services	1,069	3,56	
	I am willing to participate in events and promotions from my e-wallet	1,088	3,42	
	I am willing to leave positive feedback about my e-wallet on any platform	1,017	3,58	

Source: Author's team processing survey data (2023)

Through the descriptive statistical analysis, the authors observed that the majority of e-wallet users were satisfied with the intelligent communication system (\bar{x} =3.76), interactive personalization features (\bar{x} =4.10), and informative personalization (\bar{x} =3.64) of their preferred e-wallet brand. However, they maintained a neutral attitude towards actively collected information (\bar{x} =3.06). Nevertheless, this did not significantly affect their satisfaction with the user experience (\bar{x} =3.85), and users agreed that there was a brand love between them and their preferred e-wallet (\bar{x} =3.60).

The data shows that the factor group "Interactive personalization" has the highest average value, indicating that users of their favorite e-wallet are quite satisfied with marketing activities accessed through interactive experiences. The three highest average value statements are: "I can easily pay for familiar services with e-wallet" ($\bar{x}=4.16$), "I can easily operate e-wallet" ($\bar{x}=4.14$), and "I save time when using e-wallet for payment services" ($\bar{x}=4.12$). This indicates that the majority of the respondents have a positive attitude towards the "ease" and "time-saving" aspects of using their favorite e-wallet. Moreover, for the surveyed group of students who favor convenience, using e-wallets is a suitable trend for them.

Although the overall attitude of the respondents toward the "Active digital footprint" factor was neutral, a standard deviation larger than 1 indicates a significant difference in their evaluation scores. This can be explained by the users' attitudes towards tracking, specifically advertisements, promotions, and other incentives. Users may feel uncomfortable as they are concerned about information risks and security. The data shows that the majority of e-wallet users are worried when e-wallet ads unexpectedly appear on their devices or spread across social media platforms ($\bar{x}=2.79$). On the other hand, there are some individuals who are more open-minded and comfortable with providing information to enhance the personalization in their experience.

4.5. Hypothesis testing results

Based on the above analyses, the authors has summarized the results of testing the following hypotheses:

Table 8. Results of Hypothesis Testing

Hypothesis	Statement	Conclusion
H ₁	Intelligent interaction has an impact on user experience	Supported
H _{2.1}	Interactive personalization has an impact on user experience	Supported
H _{2.2}	Informative personalization has an impact on user experience	Supported
H _{3.1}	Active digital footprint has an impact on user experience	Supported
H _{3.2}	Passive digital footprint has an impact on user experience	Not supported
H ₄	User experience has an impact on brand love	Supported

Source: Summary of the authors' results, 2023

5. Discussion and Conclusion

According to the research findings, the use of e-wallets among students is influenced by various AI marketing factors, including intelligent interaction, interactive personalization, informative personalization, and active digital footprint. Regression testing was conducted, and the authors was able to synthesize the following hypotheses: (i) The passive digital footprint factor is deemed statistically insignificant and therefore cannot be accepted in the model, (ii) Interactive personalization is identified as the most influential factor on students' brand love towards e-wallets, (iii) Active digital footprint in the electronic

wallet experience affects users' willingness to leave their data and consequently their brand loyalty, (iv) Students exhibit no discernible differences in their perception of AI Marketing expressions when using e-wallets, and (v) E-wallets serve as an effective tool in connecting businesses with consumers through AI Marketing-enhanced promotions.

Therefore, to optimize the use of AI marketing in enhancing user experience and building brand loyalty among students who use e-wallets, businesses need to focus on: (i) Promoting marketing that allows users to interact two-way with the application and the community; (ii) Adjust promotions to suit the target audience because this aspect greatly affects the user experience; (iii) Developing personalized advertising that needs to be classified to reach users willing to share access data on digital platforms; (iv) Developing advantages in intelligent contact systems such as chatbots in user support. In other words, users expect the chatbot system to provide a sense of authenticity and confidence in their personal problem-solving abilities; (v) Cooperate with many partner units to provide suitable young people to meet a variety of products and services.

The study still presents certain limitations. Firstly, the sample structure of the group is not diverse, the scope of research is only in Vietnam and specifically in Hanoi city due to time, budget, and resource constraints. In addition, the study has not clarified the impact of demographic factors on the influence of AI Marketing in user experience on brand love. Depending on the culture and economy in different geographical areas, the research results may change, so further studies can be conducted in other geographical spaces to compare and contrast the results.

Abstract

Online Compulsive Buying is a problem arising from the explosion of e-commerce. By applying appropriate theoretical models, the authors have hypothesized and built models about the factors affecting Online Compulsive Buying behavior. The results show that stress, usefulness, and gender are factors that positively influence this consumption behavior. As a moderator, Usefulness increases the effect of stress on Online Shopping Addiction and decreases the effect of Self-esteem on Online Shopping Addiction. Moreover, the research team also makes recommendations for the Government of Vietnam, businesses doing business in the field of e-commerce, and consumers to limit this negative consumption behavior contributing to building a favorable healthy digital economy, and sustainability.

Keywords: *Online Compulsive Buying, Online Shopping Addiction, Online Shopping, E-Commerce, Consumer Behavior.*

1. Introduction

In recent years, e-commerce has grown rapidly all over the world. According to a research report on Cross-border e-commerce conducted by Ninja Van Group and DPD group in 6 countries in Southeast Asia (ASEAN) in 2022, the average Vietnamese consumer purchases 104 orders per year, higher than compared to the people of the following countries, which are Thailand (75 orders), Singapore and the Philippines (58 orders). Meanwhile, the average number of orders purchased in the region is 66 orders per year.

In today's consumer society, shopping is an integral part of life and the economy (Mukhopadhyay & Johar, 2009). E-commerce has many advantages but also leads to other problems and consequences, among which is the introduction of Online

Compulsive Buying (known as Online Shopping Addiction). With Internet shopping at their fingertips, it is easy for consumers to become compulsive shoppers (Lim, 2017). A meta-analysis examining shopping addiction found that the propensity for shopping addiction was more pronounced among young people (Maraz et al., 2016; Elliot, 1994; Roberts, 1998; Yurchisin & Johnson, 2004). Online Compulsive Buying has been identified in 2% of the world's population (Bighiu, 2015), while the figure among young people is higher. In Vietnam, according to a survey conducted by the authors, 33% of young people surveyed believe that they have signs of an online shopping addiction. In China, the prevalence of online shopping addiction among university students is 16.7% (Hou & Yang, 2020).

Compulsive Buying in general and Online Compulsive Buying have serious psychological, social, and financial consequences for an individual (Black et al., 2012). According to the study, people with Compulsive Buying Behavior can lead debt piled up at 58.3%, unable to cope with payments at 41.7%, criticism from acquaintances at 33.3%, and after judicial and financial performance at 8.3% (Christenson et al., 1994). Online Compulsive Buying affects all individuals in a society (Roberts & Jones, 2001). In addition, it is said that the recent global economic crisis is partly due to Compulsive Buying (Sharma et al., 2014; Gardarsdottir & Dittmar, 2012; Schneider & Kirchgassner, 2009).

Compulsory online buying is easier to come by than Offline Compulsive Buying (often referred to as Compulsive Buying) (Adamczyk, 2021). From a sociological point of view, the object of addiction is not a material good (such as a drug or a consumable) but an interaction between the addict and their subject that occurs under specific circumstances (Shaffer, 1996). Therefore, easy access to the subject of addiction is an important condition for the development of addiction. In other words, the act of buying is the addictive subject of Compulsive Shopping, so the fact that consumers can often meet online shopping easily creates more favorable conditions for consumers' development of this behavior. Therefore, the rate of Online Compulsive Buying is higher than that of offline forced purchases.

Despite appearing more and more in society, there are currently very few studies identifying predictors of Online Shopping Addiction (Sun & Wu, 2011), especially research placed in context in Vietnam. Due to Online Compulsive Buying (Online Shopping Addiction) not only creates market inefficiencies, but also increases social costs due to reduced productivity, personal bankruptcy, broken families, and ruined lives. Pursuing credit problems and psychiatric counseling costs both tax dollars and human lives. Therefore, research on factors affecting Online Compulsive Buying has been conducted by the authors to have a more comprehensive view of this behavior. From the research results, the authors proposed suitable solutions for behavior restriction contributing to the development of e-commerce and the digital economy in Vietnam.

2. Literature review

2.1. Online Compulsive Buying (OCB)

Online Compulsive Buying is derived from Compulsive Buying. In the beginning, purchasing was done offline, so only the term Compulsive Buying was used. Later, when technology developed, buying behavior took place on the Internet; so, the term Online Compulsive Buying was born and had a difference in the feature of online purchases to the concept of compulsive purchase. A variety of terms have been developed in this area including: "compulsive buying" (O'Guinn & Faber, 1989; Workman & Paper, 2010), and "compulsory consumption" (Faber et al., 1987; Hirschman, 1992); Compulsive Shopping Disorder or Shopping Addiction (Sussman, Lisha & Griffiths, 2010).

In the early 20th century, German psychiatrist Emil Kraepelin invented the term "oniomania" to describe the unstoppable impulse to buy. However, it was not until 1988 that this definition of behavior was proposed by another group of researchers. O'Guinn and Faber (1989) define compulsive buying behavior as repeated purchases that occur as a response to negative events or emotions. Meanwhile, Mueller et al (2015) consider compulsive shopping behavior as an excessive focus on shopping that turns into a desire to buy something difficult to control. Over time, compulsive buyers increasingly restrict their activities in the buying process. Definition from the perspective of Psychology, Dr. Donald Black (2007) - a professor of psychiatry from the University of Iowa School of Medicine has the view that "Shopping addiction is defined as an abnormal condition that in which, people are often obsessed with perception and buying behavior to the point of leading to conflict or crisis".

In general, although there are many ways of defining the concepts, they all have certain things in common. Adding the online factor, the characteristics of Online Compulsive Buying include: (1) Online purchase behavior is made continuously, and difficult to control; (2) Online shopping behavior is done regardless of possible consequences.

In short, it can be broadly defined as follows: *Online Compulsive Buying is purchased that are difficult to control, repeated over and over, despite possible adverse consequences.*

2.2. Hypotheses development & Research models

All theories and models such as the Theory of Reasoned Action - TRA, The Theory of Planned Behavior - TPB, the Technology Acceptance Model - TAM, and the two-factor model of compulsive purchase of Valence, d'Astous, & Fortier' can be used to explain online compulsive buying (online shopping addiction). However, when researching to find a theoretical model suitable for the research's goals, the authors found that:

First, when studying compulsive online shopping behavior Intent to perform the behavior is no longer an important factor to consider the impact of factors on the actual behavior.

The results of several studies have shown a limitation of TRA that Behavioral Intent does not always lead to Actual Behavior (Rhodes et al., 2005; Maruping et al., 2017). Similarly, according to Thompson's (1991) analysis of the TAM model, the intention to act is only the subjective probability that the user will perform the behavior.

Second, compulsive buying behavior comes from the need to buy goods to achieve a certain purpose - this is an important factor because if this need does not exist, online compulsive buying behavior can't arise.

Meanwhile, for the TPB, some scholars argue that this model ignores a person's needs before engaging in a certain action, needs that will influence the behavior regardless of the attitude the degree is expressed (Reed & Lloyd, 2021). Similarly, TRA does not have a person's needs element.

Third, it is necessary to have elements specific to the online shopping context to make a distinction between conventional Compulsive Buying and Online Compulsive Buying.

What makes forced Online Compulsive Buying different from Compulsive Buying is because of the context of consumer buying and selling on the Internet. Online Shopping Addicts are not necessarily addicted to Shopping and vice versa. Therefore, considering the features that only online shopping has, especially the usefulness that online shopping brings, will make the perspective of influencing factors be studied more comprehensively.

Combining the above analysis, the authors found that the combined use of the model of the two main factors affecting the compulsive shopping behavior of Valence, d'Astous, & Fortier, and TRA is appropriate for research purposes. Accordingly, Attitude will be expressed through Helpfulness, Influence from others are social norms, these are the two original factors in the TRA theoretical model. The authors expand the model with factors of psychological and personality characteristics that make consumers need to shop to achieve a certain purpose. Personal and psychological characteristics are the factors that reflect the need to buy, they want to buy to relieve emotions and to achieve certain expectations, and this supplement compensates for the shortcomings of the analyzed models.

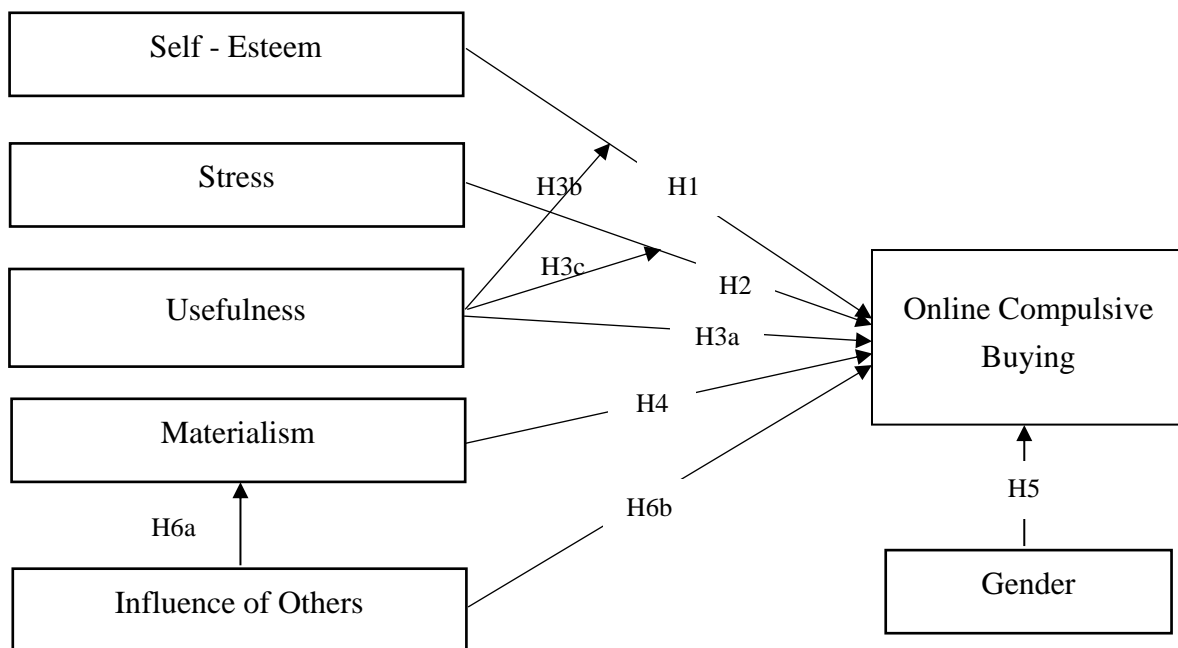

Figure 1. Research models

Source: The Authors

2.2.1. Self-esteem (SE)

Self-esteem is defined as the set of personal thoughts and feelings about self-worth and importance (Rosenberg, 1965; Orth et al., 2014). It refers to how a person perceives himself and his worth. According to the theory of self-improvement (Wicklund & Gollwitzer, 1981), when the self-perception is lower than the desired self, it will create low self-esteem, which in turn leads consumers to buy products with high self-esteem can enhance their status and true self. Therefore, the authors hypothesize:

H1: Self-esteem hurts Online Compulsive Buying in young people.

2.2.2. Stress (ST)

Stress is defined as any unpleasant emotional experience accompanied by predictable manifestations of biochemical, physiological, and behavioral changes (Baum, 1990). Emotions have been identified as a factor in continued technology use (Guinea & Markus, 2009). On the other hand, based on the theory of stress coping strategies (Folkman & Lazaeus, 1985), there are two ways that individuals manage stress. One of these is emotion-focused coping, which aims to reduce or manage emotional distress. In an emotionally focused coping strategy, some individuals will seek relief through escapism. Excessive use of shopping sites may be the result of a desire to escape reality as well as a quick distraction from discomfort and immediate relief of negative emotions (Müller et al., 2022). Therefore, the authors hypothesize that:

H2: Stress positively affects Online Compulsive Buying in young people.

2.2.3. Usefulness (US)

Perceived usefulness is defined as the degree to which a person believes that using a system will improve his or her job performance (Davis, 1989). Helpfulness stimulates more online purchases and thereby creates an opportunity for compulsive online buying behavior. Although there is no research on usefulness affecting compulsive online purchase behavior, there are many studies on the effect of the use on online purchase intention (Tunsakul, 2020; Lin & et al., 2010). Qualitative research by Astrid Muller et al (2021) states that it is important to consider certain advantages of the electronic market that contribute to the specific phenomenological characteristics of compulsive online purchases. regime.

When realizing the usefulness of online shopping, people with compulsive online shopping will trust online shopping first because of the benefits that online shopping brings. From there, for those who require psychological relief, and need to shop, the usefulness that that person perceives may increase the implementation of compulsive online purchase behavior. Therefore, the research team put forward the following hypotheses:

H3a: Usefulness has a positive effect on Online Compulsive Buying in young people

H3b: Usefulness increases the influence of Self-esteem on Online Compulsive Buying in young people

H3c: Helpfulness increases the effect of stress on Online Compulsive Buying in young people

2.2.4. Materialism (MAT)

Materialism has been conceptualized as a personality trait (Belk, 1985) and a source of life satisfaction (Richis, 1987). Materialism is a psychological construct that reflects the importance of the attainment of wealth, possessions, status, and image to an individual relative to other goals in life (Kasser, 2018). It is also described as the acquisition and use of material wealth to pursue one's goals in life or certain states (Richins, 2004). Materialists tend to improve their self-image through repeated and prolific purchases regardless of their actual need for use. Materialists turn to shop on an ongoing basis to close the gap or mismatch between the “real selves and the desired selves” (Dittmar & Drury, 2000; Yurchisin, et al., 2006). Therefore, the authors hypothesize:

H4: Materialism has a positive effect on Online Compulsive Buying in young people

2.2.5. Gender

Pratarelli & Browme (2002) provide evidence that some addictions may differ by gender. There is consistent evidence that women are more likely to exhibit compulsive and addictive buying behavior (Black 2007; Christenson et al., 1994; Davenport et al., 2012).

H5: Gender has an impact on Online Compulsive buying in young people.

2.2.6. Influence of others

The influence of others is a type of social influence in which groups of members encourage conformity and discourage nonconformity (Leary, Vann, & Groza, 2016). Several researchers have shown that influence from others influences compulsive buying (Roberts, 1998; Tan, Chen, & Theng, 2015). However, they also observed that this effect varies from the product-to-product type and from person to person (Jalees et al., 2015).

Besides, interpersonal influence including parents, teachers, and peers is one of the main causes of materialism (Chaplin & John, 2010). Individuals learn rationality from their parents and material attitudes through their peers (Churchill Jr & Moschis, 1979). It promotes social orientation and validation, leading to materialism (Chaplin & John, 2010).

H6a: Influence of others has a positive effect on Materialism

H6b: Influence of others has a positive effect on Online Compulsive Buying in young peopl

3. Method

3.1. Research instruments

The research process is divided into two phases: preliminary qualitative research and formal quantitative research.

The preliminary qualitative research method is carried out by in-depth interview techniques with experts in the field of marketing to complete the elements of the research work, thus screening the independent variables in the theoretical model.

Formal quantitative research was carried out through the survey method distributed questionnaires on the Internet. The content of the survey is divided into three parts: Part 1 is about demographic questions such as age, occupation, gender, and channels used to purchase online; In part 2, the authors use a scale to evaluate Compulsive online shopping behavior (Zhao et al., 2017) Compulsive online buying behavior is measured by a scale including 06 main factors: Importance, Tolerance, Emotional Change, Consequences of discontinuing in-person shopping, Recurrence, and Conflict; For part 3, the authors survey the factors affecting compulsive online purchasing behavior. The study used several variables that are thought to have an impact on young people's compulsive online shopping behavior such as stress (Lovibond & Lovibond, 1995), self-esteem (Rosenberg et al., 1995), usefulness (Tunsakul, 2020; Lin et al., 2010); Materialism (Richins, 2004); Influence from others (Bearden et al., 1990).

A four-point Likert scale from 1 (which didn't work for me at all) to 4 (which worked for me at all) was used to record key data for the Stress and Self-esteem scales. Meanwhile, the remaining factors are measured using a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree).

3.2. Data collection

After conducting an online survey on the Internet, with survey respondents aged from 18 to 30 years old, who have been using the online purchase method, the total number of votes collected was 639 votes. Of these, there were 171 invalid votes because they were not subject to the research and the answers were not suitable, the remaining 468 votes were valid with full information and expressed the views of the survey participants. The number of valid questionnaires included in the official data processing was 468.

Table 1. Demographic Descriptive Statistics

Gender	<ul style="list-style-type: none"> • 33.5% male • 66.5% of female
Age	<ul style="list-style-type: none"> • 30.8% aged 18-20 • 43.4% aged 21-23 • 23.3% aged 24-26 • 2.6% aged 27-30
Occupation	<ul style="list-style-type: none"> • 66.5% of students • 9.1% office workers (private enterprises) • 10% civil servants. officials • 14.4% self-employed

Source: The Authors

3.3. Data analysis

After collecting information about the subjects, the research team used SPSS and AMOS software to perform data analysis. In terms of mechanism, the characteristics of the research subjects accurately determine the group of subjects addicted to online shopping; Testing the reliability of Cronbach's alpha scale to measure observed variables; The PCA method (Principal Component Analysis) aims to reduce the scale into the main parts representing the original scales. For this study, there are a total of 68 scales, measuring 14 factors in the model; Confirmatory factor analysis (CFA) is also a method of statistical analysis used to check whether previously defined variables are consistent with the data. CFA belongs to the group of methods of factor analysis. And finally, the Linear Structural Analysis Method (SEM). The SEM method combines multiple regression analysis and factor analysis to explain complex relationships between variables.

4. Results

4.1. The results of assessing the reliability of the scale

The measured Cronbach's Alpha coefficients of the scales with Cronbach's Alpha coefficients ranged from the lowest of 0.768 of the MO components scale group to the highest of the SE component scales of 0.927. Scale correlation index - the adjusted sum of all scales is higher than 0.3, showing that all variables used have high reliability.

4.2. PCA

Experimental results show that there are 14 new representative scales extracted from the original data file of 68 original scales. The lowest measured load factor is 0.572, and the KMO coefficient is 0.880 in threshold from 0.5 to 1. In addition, using the filter extraction according to the Eigenvalue criterion is greater than 1, the number shows that the representative scale of 14 is 1,119, showing that the extracted value is 14 scales if based on the Eigenvalue criterion. The cumulative total variance in group 14 is 64,760%, indicating that these 14 representative scales can explain 64.76% of the original 68 original scales.

4.3. CFA

Evaluate the fit of the model

With the criteria for evaluating the reliability of the data file,

The value $CMIN/DF = 1.562$, is generally considered pretty good. A value below 2 or 3 is generally considered acceptable.

A CFI value = 0.920, which ranges from 0.90 to 0.95, is a moderate fit.

A TLI value = 0.914, which ranges from 0.90 to 0.95, is of average concordance.

This is the approximate error estimate of the model. A value of $RMSEA = 0.035$, less than 0.05, is considered a good fit.

In addition, the loads are shown in the table above (CFA Factor Loading) show the lowest measured load factor of 0.563 which is above the allowable threshold of 0.5.

These results show that the input data is quite compatible with the compatibility assessment model. Therefore, the model is perfectly suitable for performing other measurement experiments.

Table 2. Results of model fit

CMIN/DF	CFI	TLI	RMSEA
1.562	0.920	0.914	0.035

Source: Compiled from analysis results in Amos

Evaluate the discriminant validity and convergence of the model

The AVE (average variance extracted) values ranged from 0.509 for the WI group to the highest 0.560 for the SE group. Indicates that the explanatory percentage values of latent variables are as low as 50.9% and highest as 56%. This completely confirms that the scales achieve convergence when generalizing the concepts given, moreover the CR coefficient (the lowest composite reliability is 0.753 for the WI group and the highest is 0.927 for the SE group), more evidence is given that the measurement component scales for each concept are in perfect agreement with this experiment.

To evaluate the discriminant value of research based on the comparison method of AVE with MSV. The results show that the shared variance indices on different factor groups are always smaller than only AVE convergence. Thus, there can be confirmed that the scales are convergent.

4.4. Analysis results of Structural Equation Modeling (SEM)

The results show the impact between latent variables as follows:

Table 3. SEM model estimation results

Mối quan hệ			Unstandardized Coefficients (β)	Standardized Coefficients (β std)	S.E.	P-value
IN	----- >	MAT	1.815	1.42	0.416	0.000
ST	----- >	OCB	0.119	0.161	0.041	0.004
SE	----- >	OCB	-0.122	-0.192	0.035	0.000

Source: Compiled from analysis results in Amos

Based on the results of analyzing the relationship between variables, we have the following evaluations:

H1: Self-esteem has a negative effect on compulsive online shopping behavior in young people

This relationship is statistically significant, with $\beta = -0.122$ and $\beta_{std} = -0.192$. This shows that, as SE increases, OCB decreases. This result is in line with the expectation of hypothesis H1 and also supports the research of Bhatia (2019). Currently, when society develops, people's essential needs such as food, clothing, and learning are fully met, then people will begin to arise higher needs for self-affirmation. People with low self-esteem want to assert themselves through items, goods, and expenses that are no longer strange things in life.

H2. Stress has a positive effect on Online Compulsive Buying in young people

This relationship is statistically significant with $\beta = 0.119$ and $\beta_{std} = 0.161$. This result shows that when ST increase, OCB also increases. The results are consistent with the study of Muller et al. (2022) and the theoretical study of coping strategies for stress (Folkman & Lazaeus 1985). Online shopping behavior is a behavior that is sought to reduce stress. When shopping online, they feel liberated from reality and immersed in an online world where they can be free to choose and think according to what they like.

H3a: Usefulness has a positive effect on Online Compulsive Buying in young people

This relationship is statistically significant, with $\beta = 0.153$ and $\beta_{std} = 0.251$. This result shows when the US increases, the OCB also increases. The authors have succeeded in demonstrating that the advantageous factors of online purchasing influence compulsive online purchases. Previously, usefulness was only proven to affect the intention to perform the behavior and the intention to influence the compulsive online purchase behavior (Luong Thu Ha et al., 2021).

H3b: Usefulness increases the influence of Self-esteem on Online Compulsive Buying in young people

This relationship is statistically significant, with $\beta = -0.047$ and $\beta_{std} = -0.163$. This shows that as US_SE goes up, OCB goes down. The test results obtained are not the same as the hypothesis that the research team set out. The usefulness of online shopping makes the effect of Self-esteem on compulsive online buying behavior becomes less.

H3c: Usefulness increases the effect of stress on Online Compulsive Buying in young people

This relationship is statistically significant, with $\beta = 0.034$ and $\beta_{std} = 0.124$. This result shows that when US_ST increases, OCB also increases. The authors have succeeded in proving the moderator role hypothesis of utility. The impact of stress on online shopping addiction is also driven by usefulness. When convenience appears, consumers can easily access and approach the online store from anywhere, anytime, in any space, or at any event.

H4: Materialism has a positive effect on Online Compulsive Buying in young people

This relationship is statistically significant, with $\beta = 0.415$ and $\beta_{std} = 0.34$. This result shows that when MAT increases, OCB also increases. This result is similar to the results of previous studies that have been performed (He et al., 2018; Bhatia, 2019). In the modern consumer society, online shopping has become an important part of life and can be considered a means for people to interact with the physical world.

H5: Gender has an impact on Online Compulsive Buying in young people

This relationship is statistically significant, with $\beta = -0.107$ and $\beta_{std} = -0.136$. This result shows that when the Gender is male, OCB decreases.

H6a: Influence of others has a positive effect on materialism

This relationship is statistically significant with the unnormalized coefficient (β) of 1.815 and the standardized coefficient (β_{std}) of 1.42. This shows that, as IN increases, MAT also increases. This result is consistent with previous studies.

H6b: Influence of others has a positive effect on Online Compulsive Buying in young people

This relationship was not statistically significant ($P\text{-value} > 0.05$). This shows that there is no statistical evidence to confirm the relationship between IN and OCB.

5. Discussion and Conclusion

Based on the Theory of Reasoned Action (TRA) and Valence, d'Astous & Fortier's Compulsive Buying model, the authors have constructed a model of factors influencing Online Compulsive Buying (online shopping addictions) among young people. Through research, there are a total of 5 factors identified to have an impact on Online compulsive buying (online shopping addiction) among young people, namely: Materialism, Stress, Self-esteem, materialism, and finally, Gender. For the factor of Influence of Others, there is no statistical evidence to confirm the relationship between this factor and compulsive online shopping behavior (online shopping addiction).

With these results, the research team has made theoretical contributions to the research topic on behaviors related to Online Shopping in general and Online Compulsive Buying in particular. At the same time, the authors also make some recommendations as follows:

For consumers who need to overcome compulsive online shopping habits, it may be helpful to consider replacing shopping with other healthy and beneficial lifestyles to alleviate psychological issues. Therefore, the first step in preventing compulsive shopping behavior is identifying the psychological needs that drive it.

In cases where everything seems to be getting out of control, individuals may need to seek immediate treatment if they cannot find alternative ways to relieve stress other than online shopping. There is always a reason behind negative emotions, and counseling professionals can help eliminate these negative feelings.

Individuals need to have a more accurate understanding of the definition of success and its value to themselves. Value can be built by developing oneself through courses and social activities, instead of emphasizing external material value. Developing emotional intelligence skills can contribute to more sustainable consumer behavior, and reduce susceptibility to materialism, and therefore, the consequences of addictive behavior.

Engaging in non-shopping related activities such as sports, book clubs, or cooking can help compulsive shoppers partially forget their addictive behavior and become acquainted with new habits.

For the government, appropriate regulations should be established based on consideration of the negative impacts of this behavior to protect the rights of consumers, promote the healthy development of e-commerce towards positive consumer behavior, and sustainable and environmentally friendly shopping. Therefore, there should be regulations for e-commerce platforms regarding the establishment of limits and restrictions on customers' shopping accounts. Limits and restrictions can be set on consumers' online shopping accounts to help them maintain control and limit their spending. For example, reminders can be set for online shopping time, where the longer they shop online, the more discounts decrease over time. The government can develop programs to enhance business awareness of sustainable economic development. In addition, the government should create favorable conditions for companies participating in sustainable economic activities in e-commerce. Regarding regulatory management for other relevant entities such as credit cards and consumer lending channels, the state needs stricter measures to minimize payment tools and reduce addictive online shopping behaviors. In practice, anyone can open a credit card from VND 15-30 million without having to prove their financial status, which has become leverage for the forced development of online shopping behavior

From a business perspective, it is evident that online businesses participating in this activity can leverage the factors that coerce consumers to make more purchases. Therefore, businesses play an equally important role in generating and developing consumer behavior. Businesses should consider implementing reasonable advertising and consumption policies that both limit the negative impacts of such behavior and contribute to creating a healthy and stable business environment. Striking a balance does not mean that businesses' measures must eliminate coerced online shopping behavior and reduce business revenue.

Abstract

In the current era of 4th industrial revolution, accelerating digital finance is becoming more and more popular in the commercial banking system. Digital finance assists in bank stability; however, it may also pose the chances of financial instability due to systematic risks. Consequently, the purpose of this paper is to conduct the impact of digital finance on banking system stability, thereby providing policy implications related to digital finance in order to promote Vietnamese's inclusive finance. This paper uses Random Effect Model (REM) to investigate empirical evidence on the impact of digital finance on 24 commercial banks in Vietnam between 2013-2022. The result suggests that digital finance leads to economic growth and enhances banking performance in the future. However, for some emerging markets like Vietnam, there is a negative relationship between digital finance and bank stability in short term. This can be explained by the fact that the practice of digital finance in Vietnam is at the very early stage that takes some time to impact positively on the banking stability and consequently the economy as a whole. Therefore, the government, policymakers can consider digital finance as an effective tool in order to bring a revolutionary development in overall financial sector.

Keywords: *commercial banking, digital finance, stability*

1. Introduction

In recent years, the trend of using digital services in banking activities has become prominent with the increasing number of customers participating and the increasingly diverse types of services. Especially since 2020, when the Covid-19 epidemic broke out, digital finance has become one of the typical features of the current financial landscape.

According to research by Kasri et al (2022), digital payments are being used more by nearly 50% of consumers globally. Of those, most plan to continue using it in the future. According to a report published in December 2021 by the Bank for International Settlements (BIS) on nearly 30 economies in the period 2020 - 2021 compiled by the Committee on Payments and Market Infrastructure (CPMI). In general, the total value of non-cash payments has a high growth rate (State Bank of Vietnam, 2022). Along with that, the stability of the banking system is one of the top concerns of bank managers, deposit insurers and the general public due to the potential for system-wide contagion (Bai and Elyasiani, 2013). Therefore, the impact of digital finance on the stability of the banking system is a topic of current concern. The development of digital finance can bring about decentralization and diversification, efficiency and transparency (Vučinić, 2020), and create incentives for banks to lend to more individuals and businesses. and leads to diversified benefits (Danisman & Tarazi, 2020) (Stephane et al, 2019). Therefore, studies in developed countries and a number of research papers in developing countries suggest that digital finance can generate profits and bring many positive effects to ensure sustainable economic growth in times of crisis such as the Covid-19 pandemic (Banna and Alam, 2021), (Du Thi Lan Quynh, 2021), (Safiullah and Paramati, 2022), (Hasan et al, (2022), (Banna et al , 2021), (Syed et al, 2022), (Lin et al, 2022) However, with some studies in developing countries, there are different opinions about the influence of digital finance on banking stability. According to Syed et al (2021) that digital finance can cause systemic risk and financial instability through empirical research in three South Asian countries (India, Pakistan, Bangladesh). In addition, differences in short-term and long-term results also occur in some studies in developing countries such as Syed et al (2022), Kasri et al. associates (2022)

In Vietnam, by the end of April 2022, non-cash payment activities had a high growth rate compared to the same period last year (State Bank of Vietnam, 2022). In which, compared to the same period in 2021, in terms of quantity, statistics show that contactless payment transactions increased by 69.7%, Internet transactions increased by 48.39%, QR Code transactions increased by 56.52% and via mobile phones increased by 97.65%. In addition, the number of activated e-wallets also increased by a total of 10.37% compared to the end of last year and the number of Mobile Banking transactions is also estimated to reach a growth rate of 200%. In addition, every day Vietnam has about 30 million people using the Internet banking payment system with the value of private money transactions at the mobile phone channel reaching 300 trillion VND/day. According to data announced at the press conference of the series of events in response to "Cashless Day 2022" held on May 20, 2022, the first 4 months of 2022 have achieved a growth of 32.37% in transaction value through the interbank electronic payment system.

Therefore, studying the impact of digital finance on the stability of the commercial banking system in Vietnam is of practical significance to provide a deeper insight into the relationship between digital finance and the stability of the banking system. Then, our goal is to help commercial banks make the right decisions about applying digital finance in their operations to ensure financial stability in the future.

The article has applied the predecessor theoretical basis to propose a research model, collected panel data from 24 Vietnamese commercial banks and the economic growth rate and inflation rate of Vietnam in the period from 2013 to 2022, using panel data estimation techniques by random effects regression (REM) to investigate empirical evidence on the impact of digital finance on the standard deviation of ROAA and Zscore from which the article proposed some policy implications related to the research results

2. Method

The research was written based on the work of *Banna (2021)*, in which the research group adjusted the appropriate factors to measure the impact of digital finances on the stability of the commercial banking system in Vietnam. The research was conducted in a situation where many countries are moving towards a cashless economy by implementing new technological services. In particular, in Vietnam - a region with financial diversity, more emphasis is being placed on the expansion of technology into the financial market. Furthermore, several financial institutions including the banking sector, rely on technology to provide digital financial services.

The research was carried out using quantitative research methods with secondary data sets from 24 commercial banks over the 10-year period from 2013 to 2022 and it includes reports on macroeconomic variables, digital finances and stability banks. The model proposed by the research team includes 2 dependent variables: i) Ln(Z-score) using return on average assets (LZS), ii) Volatility of ROAA (SDROAA) and 10 independent variables, of which there are 6 bank-specific variables: i) Loan ratio (LR), ii) Loan loss provision ratio (LLPR), iii) Management quality (MQ), iv) Capitalisation (equity ratio) (CAP), v) Revenue diversification (IND), vi) Bank size (SIZE). 2 macroeconomic variables: i) GDPG: Gross domestic product rate, ii) INFL: Inflation. 2 digital financial variables: i) INT: The percentage of the population using the Internet, ii) MMT: Mobile money transaction percent of GDP.

In regard to the quantitative method, the research group used the Stata 14 software program to measure the impact between the independent and dependent variables, conduct hypothesis testing through a multivariate regression model and evaluate the results based on certain standards. Accordingly, the economic data are grouped into the software in the form of a panel data model consisting of two components: cross-section data and time series data.

Based on the original research of Hasanul Banna and Md Rabiul Alam (2021), the research model applied in the study follows as:

$$Y_{ijt} = \beta_0 + \beta_1 DF_{jt} + \beta_2 B_{ijt} + \beta_3 M_{jt} + \epsilon$$

In there:

Y_{ijt} : ln (Z-score) and ln (SDROAA) are dependent variables representing the stability of bank i in country j in year t

DF_{jt} : Digital financial index of country j in year t

B_{ijt} : Banking factors of bank i in country j in year t

Mjt: Macroeconomic factors of country j in year t

β_0 : Intercept factor

$\beta_1, \beta_2, \beta_3$: Coefficients of the independent variable

ϵ : Model error

3. Results

3.1. Correlation analysis

The correlation coefficient (r) is a statistical indicator that reflects the degree of linear relationship between variables. The r value ranges from -1 to +1 regardless of the measurement size of the variables. Through the correlation coefficient r , it is possible to know the individual correlation direction between the variables and detect the phenomenon of multicollinearity (if $r > 0.8$). In addition, when the pairwise correlation between variables is high (greater than 0.5), multicollinearity can occur (Gujarati, 2008). This can lead to the model having high multicollinearity defects; at the same time, the estimated coefficients easily lose their statistical significance and their sign is opposite to the expected sign; The estimated results are unreliable.

According to the results presented in the table, there is no pair of correlation coefficients greater than 0.8, so the correlation between variables is at an acceptable level. Therefore, this is an important basis to help the authors test and select the appropriate model.

Table 1. Correlation coefficient matrix

3.2. The model tests for multicollinearity

The research team continues to perform the test to check the phenomenon of multicollinearity based on the Variance Inflation Factor (VIF). In which, if $VIF > 10$, there is multicollinearity phenomenon, which can seriously affect the estimated results of the model. Based on Table 2, the VIF coefficients of all 10 factors are less than 3 and the average VIF is 1.38, inferring no multicollinearity with the selected variables. Therefore, the research team kept the above variables unchanged to perform other regressions.

Table 2. Result of multicollinearity test among independent variables

Variables	VIF	1/VIF

3.3. Random effects model (REM)

The research team runs Hausman test to find out the most accurate and sure fit for the collected data set, which is the FEM or REM model. The Hausman test poses two hypotheses:

H0: REM random effects model is suitable and effective

H1: The FEM fixed-effects model is suitable and effective

The results show that in model 1 $\text{Prob} > \chi^2 = 0.5090 > 0.05$ and in model 2 $\text{Prob} > \chi^2 = 0.7292 > 0.05$. With 95% confidence, we do not have enough basis to reject H0. Understandably, the random effects model REM is the most suitable model for data analysis.

Table 3. Model estimation results by REM method for the period of 2013 - 2022

3.4. Verification and correction of defects

To identify the defects of the model, the research team conducted a test of the variable variance phenomenon (Breusch Pagan Lagrangian Multiplier test) and the autocorrelation phenomenon (Woodridge test). After obtaining the test results, the authors conclude that both models suffer from the above defects. Therefore, the team used the FGLS model with a selection of panels (heteroskedasticity) and corr (ar1) to overcome the defect.

4. Discussion and Conclusion

4.1. Discussion

Digital finance is the bridge to improve the well-being of individuals and businesses who have official bank accounts and have funds in their bank accounts to complete many financial transactions. Policymakers of state agencies and business managers have always strived to promote digital finance. This study focuses on analyzing the impact of digital finance on the stability of the commercial banking system in Vietnam in the ten years from 2013 to 2022, thereby providing some recommendations. The research group chooses to measure digital finance through the percentage of mobile payments on GDP proposed by Siddik and Kabiraj (2020). At the same time, we choose the Z-score and the volatility of return on average assets (SdROAA) as variables representing the banking system's stability.

Based on synthesizing secondary data from 24 commercial banks in Vietnam over the ten years from 2013 to 2022, using panel data analyzed by the Random-Effects Model, The research team has concluded that the model consists of 8 factors that affect two dependent variables, ln (Z-score) and ln (SDROAA) with a significant explanation rate of 31.86% and 40, respectively.

The results of the research team indicated that bank size (SIZE) had a positive effect on the average return on assets (ln Z-score) and a negative impact on variation in average return on assets (SDROAA) over the entire study period from 2013 to 2022. This result could explain that when banks are large, credit ratings become more severe, and banks tend to accept less credit in return for higher quality (Boot and Thakor, 2000). Besides, according

to Hughes et al. (2001), large banks can gain potential diversification advantages, thereby increasing the bank's operational efficiency and profitability and promoting the bank's stability. This result is also consistent with previous studies by Haan and Poghosyan (2012), Adusei (2015), and Banna and Alam (2021).

The loan ratio (LR) had a positive effect on the stability of the banking system. The experimental test of Fang et al. (2014) and Fukuyama et al. (2022) also gave similar results. Lending is one of the main activities that bring the majority of profits to banks, so when banks lend more, profits and stability also increase. Compared to banks that prefer to invest in non-traditional activities or derivatives, banks with higher loan ratios tend to be less risky.

The loan loss provision ratio (LLPR) negatively affected the banking system's stability. The higher the provision ratio, the lower the banking system's stability, and vice versa. The increase in the risk provision ratio is a sign that the bank is pursuing risky lending activities and may cause instability in the system (Ahamed and Mallick, 2019). When a bank's bad debt ratio is high, the risk provision becomes larger, increasing the bank's operating costs.

Management quality (MQ) measured by total profitable assets over total assets of a bank had a positive relationship with the banking system's steadiness. When the ratio of earning assets is higher, the bank's management quality becomes better, thereby reducing excessive risk-taking and making the banking system more stable (Ahamed and Mallick, 2019).

The capitalization (CAP) positively affects the banking system's firmness through its relationship with $\ln(\text{Z-score})$ but also increases ROAA volatility, which means increased volatility. The equity ratio is the internal strength of commercial banks, indicating the financial autonomy of those banks. Well-capitalized banks are perceived to be less risky, thereby maintaining bank stability (Berger et al., 2009). According to Gambacorta and Mistrulli (2004), a higher equity ratio will increase the bank's stability, especially in times of crisis.

The revenue diversification (IND) is not statistically significant when regression of the full-sample model 2013-2022. In the REM model, IND has a positive effect on the banking system's stability. When studying income diversification in 11 developing economies, Sanya and Wolfe (2011) found that diversifying activities that generate interest and non-interest income can significantly reduce the risk of insolvency, thereby increasing the bank's stability.

The result showed that the percentage of mobile payments to gross domestic product (MMT) had a negative influence on the banking system's stability. This result contradicts the study of Stephane et al. (2019); Banna (2020, 2021); Risman et al. (2021) when these authors concluded that digital finance had a positive impact on financial stability by increasing the ability of banks to provide financing.

The percentage of the population using the Internet (INT) - the variable used to measure digital finance - increases, and the banking system's stability increases. In the long term, as the number of Internet users increases and knowledge about digital finance is more

widely available, the official digital financial products of banks will also become easier to access. Banks are more convenient in customer management and increase the stability of the system (Siddik and Kabiraj, 2020).

Considering the variables of macroeconomic factors, the research team's model results show that the inflation rate had no impact on stability. When regressing using the FGLS model, the GDP growth rate showed a positive relationship with stability. As the economy develops, the banking system's firmness is also promoted (Honohan, 2008; Ozili, 2018).

4.2. Conclusion

The research team has collected data from macro statistics and financial statements of 24 Vietnamese commercial banks from 2013 to 2022, fully satisfying the selection conditions of the authors. After that, the data is entered into STATA software to conduct regression analysis according to the panel data regression method (Panel Data Regression) with the approach of all three models involving Pooled OLS model (pooled OLS model), fixed effects model (FEM), and random effects model (REM). The research shows that eight factors affect the stability of the banking system, where the primary variable is digital finance as measured by the percentage of mobile payments to GDP which has a negative effect on the stability of the banking system. The sample in the author's research paper is Vietnam - a country that has only developed digital finance in the last few years. Therefore, it will probably need more time to prove the relationship between these two variables. Moreover, there needs to be a technology background with strong information coverage so that digital finance can flourish and promote the banking system's stability.

Overall, this study shows a solid significance on determinants that influence the banking system's stability in Vietnam. The findings should be recommended for adopting a better digital financial system, thereby developing the banking system's stability, not stifling it. Some of the recommendations are illustrated below:

- The central bank needs policies to promote commercial banks to complete and build a firm information technology apparatus so that digital finance can enhance stability. State agencies need to accelerate the process of completing legal regulations on electronic transactions and developing regulations on the protection of personal data and the privacy of service users.
- The central bank should complete the overall financial capacity improvement project, then set specific capital increase milestones for each bank.
- State agencies should continue to find solutions to stimulate economic growth, control inflation, and develop a sustainable economy.
- Commercial banks should study and build a complete roadmap to change the model to digital banking.
- Commercial banks should focus on developing smart banking products and services, such as e-wallets with relative ecosystems.

- Banks should focus on comprehensive consolidation, such as improving the bank's inefficient asset ratio, raising the capital-to-total asset ratio, and adjusting state ownership for individual banks. It will increase the stability of that bank and simultaneously contribute to promoting financial inclusion, thereby devoting itself to the steadiness of the whole financial system.

4.3. Limitations and further research directions

The scope of coverage of digital finance is broad. In this study, the authors only focus on mobile money transactions. This variable cannot represent the entire digital finance. Similarly, the stability of a bank can be measured by many variables; however, in this paper, only the Z-score and volatility of return on average assets (SdROAA) are used as a proxy. Moreover, the study only focuses on sampling data in Vietnam, there has not been an expansion of the research scope to other countries in the region and the world.

Based on the above limitations, future studies can expand the scope of research to countries and regions in the world. In addition, future studies may add other variables to the model as well as select other measures for digital finance and the banking system's stability.

National Economics University, Hanoi, Vietnam

Abstract

This study was conducted to measure and evaluate the financial literacy of Vietnamese students and to determine the factors affecting the financial literacy of this group in the context of digital transformation. Using data collected from 1,114 students at different universities in Hanoi, the authors applied Cronbach's Alpha, EFA, One_Way ANOVA techniques, and obtained the most significant results: Vietnamese students have financial knowledge, financial attitudes, financial behavior, and financial literacy, in general, are at a good level. There is a statistically significant difference in the financial literacy scores between this group by Gender, Education, Having bank accounts, using Smart Banking, and Investing online. Accordingly, male students show higher scores in financial literacy than female students. Students majoring in engineering, economics and business administration have higher levels of financial literacy than those in languages and other majors. In connection with the digital transformation in Vietnam, the fact that students have bank accounts, use Smart Banking, and make online investments has helped to increase literacy levels. These new and valuable findings represent another positive influence of digital transformation - besides the impact on the business development of enterprises and customer satisfaction (which has been mentioned in many newspapers, reports, and other studies).

Keywords: *financial literacy, students, digital transformation*

1. Introduction

According to the OECD (2013), Financial Literacy (FL) is the combination of awareness, knowledge, skills, attitudes and behaviors required to make meaningful reliable financial decisions to achieve personal financial satisfaction. Improving an individual's FL not only ensures the reduction of financial risks when participating in and using financial

services, but also has an important meaning and positive impact on the financial inclusion of each country (Grohmann et.al, 2018). However, on the 2018 financial inclusion index, Vietnam ranked only 112/176 in the world and 23/37 in Asia. According to a research sample by Dougn (2019), only 24% of the Vietnamese surveyed had an above-average FL. In general, the FL of Vietnamese people is still limited (Do Hong Nhung and Nguyen Ngoc Hai Chau, 2021). This fact motivates researchers to consider and evaluate the level of FL of Vietnamese residents (particularly young people, accounting for 21% of the population in 2019), and to identify factors affecting FL, which provides the scientific basis for appropriate solutions to improve FL. In order to meet this requirement, several studies have been conducted, focusing on evaluating the FL of students in Vietnam such as Le Hoang Anh et.al. (2018), Tran Thanh Thu et.al. (2021). However, no author has considered the FL of the youth in the context of digital transformation in Vietnam.

Digital transformation is the integration of digital technology into all areas of an enterprise, creating a fundamental change in the way of operation and business model in order to increase enterprise value and customer satisfaction. The digital transformation process in Vietnam up to 2022 has recorded important results, typically the digital economy accounts for 10.41% of GDP (an increase of 9.6% compared to the end of 2021)¹. Digital transformation brings businesses many advantages such as saving operating costs, improving access to customers, increasing accuracy and speeding up the decision-making process, and improving productivity, thereby increasing the operational efficiency and competitiveness of enterprises. On the other hand, digital transformation is an inevitable “path” for businesses to cater to the Gen Z customer group, which currently accounts for 32% of the world population. This is a group of people who are tech-savvy and willing to experience innovation and invention. According to experts, the path of digital transformation depends on the current status and financial capacity of each enterprise, but they must aim at customer experience and satisfaction. This results in the Vietnamese students being able to search and order anything via websites, e-commerce platforms, social networks and shopping apps. In particular, they easily compare prices and use sales promotion programs to get satisfied products at the lowest cost. In addition to the popularity of e-wallet applications, Smart Banking is an important premise for transactions to be carried out entirely online. In addition, digital transformation also helps students save and invest in online platforms and smartphones. Consequently, the process of consuming and managing personal finances is quick, convenient and flexible.

Based on the above analysis, the research group believes that the activeness of enterprise in digital transformation enables Vietnamese young people to access financial issues earlier and more conveniently, improving the FL of this group compared to previous generations. In order to scientifically and reliably verify this judgment, the authors conduct research to measure FL and determine factors affecting the FL of students at some universities in Hanoi. Among the expected factors, purchasing goods on e-commerce platforms, using shopping apps and online payment, using Smart Banking and investing online are representative factors of digital transformation.

2. Literature Review

Financial literacy (FL) is a multidimensional concept - a term that is common and used all over the world. So far, many researchers have offered different concepts and explanations (Holzmann, 2010; Hung et al., 2009; Morgan and Trinh, 2017...). However, the most commonly used concept of FL is still the concept of OECD (2013) mentioned above. Since then, OECD (2013) has developed a set of questions to measure individuals' financial literacy in general. However, in 2022, the OECD adjusted the questionnaire and focused on measuring FL using 3 main aspects: Financial Knowledge, Financial Behavior and Financial Attitude. The content of each aspect is understood according to the interpretation of the World Bank (2013), specifically: *Financial knowledge* is an individual's understanding of basic financial concepts (inflation, compound interest,...) and how to recognize financial products/services as well as basic financial skills (payments, bank account...). Therefore, financial knowledge is a prerequisite for shaping financial attitudes and behaviors of each individual. *Financial Attitude* is an individual's view of the surrounding financial situation, including attitudes about saving, investing, borrowing, attitudes toward the future, and self-confidence toward retirement plans, saving trends, lending... Determining an individual's attitude towards economics and finance is a consequence of that individual's financial knowledge and creates a premise for financial behavior (financial decision making). Finally, *financial behavior* is understood as an individual influence on the volatility of financial issues around such as daily money management, long-term planning, making financial decisions (the ability to choose the right financial products) or seeking financial advice. Through individual's responses to financial issues, we can evaluate an individual's sensitivity to financial in the face of change.

Regarding the main factors affecting individual's FL, these are age, gender, and education level, based on strongly corroborated studies. Specifically, for students aged 15 to 22, Edwy et. al (2022) proved that FL increases with age. According to the author, as age increases, people become more knowledgeable, leading to a change in their attitudes and behavior. This result is confirmed by Le Hoang Anh et. al (2018). According to the research of Utami and Sitanggang (2021), university students have higher levels of financial literacy than high school students.

There are also gender differences in financial literacy. Research by Chen and Volpe (2002), Eitel and Martin (2009), Nguyen Thi Hai Yen (2015), Philippas and Avdoulas (2019) confirmed that men are financially savvy better than women. Meanwhile, Nguyen Thi Yen (2014), Nguyen Dang Tue (2017), and Le Hoang Anh et. al (2018) found the opposite result.

Regarding education, Philippas and Avdoulas (2019) point out that university students with Economics majors have better FL than students with other majors because they have access to financial knowledge at school. In addition, financial perception is also influenced by the number of years attending university: 3rd and 4th year students have better FL than 1st and 2nd year students. This result is supported by Le Hoang Anh et al (2018), Morgan and Trinh (2017), Pham Thi Hoang Anh et. al (2021), Tran Thanh Thu et. al (2021).

In addition, it had been found that income, occupation, and culture and living environment factors have a positive impact on an individual's FL (Pham Thi Hoang Anh et

al., 2021; Philippas and Avdoulas, 2019; Thapa et al., 2015). However, the factors associated with the digital transformation process have not been considered clearly and comprehensively, especially in Vietnam. However, a number of researchers around the world have proposed the relationship between the benefits of establishment through digital transformation and the FL of young people. According to Suratno et al (2021), students having the habit of online shopping have higher levels of FL than those who do not shop online because they are more agile when comparing prices on e-commerce platforms and understand product information better. Furthermore, Seldal and Nyhus (2022) state that today's young people are the group of people who use online payments most often, and that students who use online payment services have better FL than those who do not use this service. With regard to saving and investment behavior, Michaela et. al (2022) concluded that students who participate in investment activities have higher levels of FL because they have knowledge of choosing the right investment tools as well as an understanding of the benefits and risks of investment.

3. Method

3.1. Financial literacy scale and influencing factors

To measure financial literacy (FL), the authors use the concept and the questionnaire from OECD (2022), which, however, is selectively adapted to the age of 18 to 22 in Vietnam. FL is measured on three dimensions including financial knowledge, financial attitudes, and financial behavior. Specifically, the Financial knowledge variable is measured using 7 scales which are questions that test respondents' understanding of the time value of money, inflation, interest rates, savings, loans, investment, risk. Each question has specific answers and is then converted to a 5-point Likert scale from (1) respondents have no knowledge to (5) Respondents have reasonable knowledge of the question asked.

Table 1. Scale of Financial Knowledge variable

Symbol	Contents of the scale
K1	If you were given 100 million VND, would you like to receive it now or in 5 years, knowing the price of everything you want to buy stays the same in those 5 years?
K2	When the inflation rate increases, how will the money that you have to spend on daily living?
K3	Assume that you need to buy a laptop for 15 million. Store A offers a discount of 2 million, store B 10% off. Which store do you choose to buy from?
K4	You have 100 million VND in savings at the bank with an interest rate of 8%/year. After 2 years, what amount will you get?
K5	Today, you save money at the bank with an interest rate of 8%/year. If the inflation rate is 10%/year, after a year, what will this money be worth compared to now?
K6	You borrow 100 million from the bank, after 1 year you have to pay 106 million. What is the loan interest rate?
K7	Is it always better to split your investment into several different asset classes than to invest in a single one?

The Financial Attitude variable measures the thoughts or beliefs of each person about financial matters, measured by a 6 Likert scale with 5 points from (1) Totally disagree to (5) Totally agree.

Table 2. Scale of Financial Attitude variable

Symbol	Contents of the scale
A1	I find setting up a spending plan is necessary
A2	I find comparing and finding out the price before buying is necessary
A3	I find saving part of my income instead of spending it all is necessary
A4	I only borrow money when absolutely necessary (for compulsory expenses for living and studying)
A5	I think it is better to deposit my savings in a bank to receive a stable and safe interest rate than to invest in the stock market, cryptocurrency or business.
A6	I find diversifying investment activities is necessary

Financial Behavior variable represents an individual's specific response to changes in economic and financial fields, measured by a 6 Likert scale with 5 points ranging from (1) Totally disagree to (5) Totally agree.

Table 3. Scale of Financial Behavior variable

Symbol	Contents of the scale
B1	I strictly adhere to the spending plan
B2	I always compare prices before buying
B3	I regularly leave part of my monthly earnings for urgent future needs
B4	I rarely have to borrow money to spend
B5	I deposited savings instead of investing in stocks, cryptocurrencies, business,...
B6	I usually diversify my investments

Based on research literature, the factors affecting financial literacy include gender, age, education, and digital transformation factors (table 4).

Table 4. Scale of influencing factors

Variable name	Symbol	Contents of the scale
Gender	Gender	Gender
Age	Age	Age
Major	Edu	Major
Digital transformation	DT 1	Buy on e-commerce platform
	DT 2	Use shopping and payment apps on smartphones
	DT 3	Have your own bank account and use Smart Banking service
	DT 4	Interested in and making online investments

3.2. Research sample

Based on the allocation of 1,300 surveys directly to students in different universities in Hanoi in the period from December 2022 to February 2023, the research group received 1,114 responses qualified for analysis. The results are shown in Table 5.

Table 5. Structure of the research sample

Factor	Classification Criteria	Quantity	Percentage
Gender	Male	447	40.13%
	Female	661	59.34%
	Other	6	0.54%
Age	18	317	28.46%
	19	231	20.74%
	20	329	29.53%
	21	143	12.84%
	22	94	8.44%
Major	Engineering	264	23.70%
	Language	153	13.73%
	Economics and Business Administration	588	52.78%
	Other	109	9.78%
Buying on e-commerce platform	No	249	22.35%
	Yes	865	77.65%
Using shopping apps and online payment	No	176	15.80%
	Yes	938	84.20%
Having bank accounts	No bank account	25	2.24%
	Having a bank account, do not use Smart Banking	109	9.78%
	Having a bank account and use Smart Banking	980	87.97%
Investing online	Not interested in online investment	377	33.84%
	Interested, but not invested online yet	633	56.82%
	Interested and have online investment	104	9.34%

The above sample structure shows that the percentage of surveyed females is higher than that of males, mostly between the ages of 18 and 20. The number of surveyed students studying Economics and Business Administration is dominant among those studying engineering and language majors, which corresponds to the educational scope of the universities in Hanoi. Regarding digital transformation background, businesses that are actively changing the way they provide services have been making online purchases and payments, using Smart Banking and online investment become popular, especially after the outbreak of Covid 19 pandemic in early 2020. In the survey sample, 77.65% of students shop

on e-commerce platforms, 84.2% of them use online shopping and payment apps, and 87.97% of them have Bank accounts and use Smart Banking. This number is much higher than the average of 68% of the Vietnamese population who have a bank account². Also, regarding online investment activities, due to new capital requirements, and a certain level of understanding, the percentage of students investing online reaches 9.34%, while the proportion of students being interested in online investment (although not yet implemented) is 56.82%, accounting for more than a half of the research sample, demonstrating the sharp sensitivity and quick grasping to new trends of young people.

3.3. Data processing techniques

The following are the primary data processing techniques used for the research:

First, descriptive statistics. Frequency statistics to determine the sample structure. Mean statistics are used to describe the survey subjects' overall assessment of how many points are used on the scale (Likert 5), with an emphasis on the Mean, Max, Min, Standard Deviation.

Second, evaluate the reliability of Cronbach's Alpha. Cronbach's Alpha is used to evaluate termite relationships between variables in the same group. According to Hoang Trong and Chu Nguyen Mong Ngoc (2008), the value of Cronbach's Alpha coefficient from 0.6 or higher is the qualifying scale. Corrected Item - Total Correlation represents the relationship between an observed variable and all other observable variables on the same scale. According to Loiacono (2000), this coefficient should be set to ≥ 0.4 in order to select the best observational variables for a measurement scale.

Third, Exploratory Factor Analysis (EFA). EFA is used to reduce a set of many variables to measure interdependence into a smaller set of variables (called factors), ensuring that they are more significant but still contain most of the information content of the original set of variables. According to Hair et al. (2009), Factor loading with a value of 0.5 or higher, the new observed variable is evaluated as "statistically significant." In addition, the value of KMO must reach a value of 0.5 or higher as a sufficient condition for the factor analysis to be appropriate. Bartlett's assessment is statistically significant (Sig. < 0.05), showing that the observed variables are as a whole correlated. In addition, the total variance explained $\geq 50\%$ indicates that the EFA model is appropriate.

Fourth, One-way ANOVA. This analysis shows differences in FL between different groups in the same factor as shown in Table 5. In the Homogeneity test table, if Sig. value of Levene Statistic ≥ 0.05 shows that the variance between the choices of the qualitative variable is not different, see the results in the ANOVA table. If F's Sig. value in ANOVA rating table is < 0.05 , it can be concluded: There are statistically significant differences in the FL levels of different students in each group. In case Sig. value of Levene Statistic $< 0,05$, the equation hypothesis between groups of qualitative variables is violated. Then, look at the Robust Tests test table, if Welch's Sig. value is $<0,05$, it shows that there is a statistically significant

² <https://vnexpress.net/68-nguoi-truong-thanh-co-tai-khoan-ngan-hang-4477351.html>

difference in the levels of FL between the groups being considered. Specific differences between groups are expressed in the size of the Mean values in the Descriptives table (if there are only two classified groups) or Mean Difference and Sig. values on the Multiple Comparisons table of the Post Hoc query (if two or more classified teams are included).

4. Results

4.1. Assess the reliability of the scales for each aspect of Financial Literacy

By conducting the Cronbach's Alpha reliability test for each group of Financial Literacy, Financial Attitude, and Financial Behavior scales, the following results were obtained, as shown in Table 6.

Table 6. Summary of Reliability Statistics

Variable	Scale	Corrected Item-Total Correlation	Cronbach's Alpha if Item Deleted	Cronbach's Alpha
Financial Knowledge	K1	0.187	0.641	0.633
	K2	0.264	0.620	
	K3	0.340	0.602	
	K4	0.366	0.591	
	K5	0.452	0.557	
	K6	0.500	0.547	
	K7	0.333	0.601	
Financial Attitude	A1	0.526	0.607	0.684
	A2	0.572	0.599	
	A3	0.582	0.594	
	A4	0.440	0.636	
	A5	0.125	0.742	
	A6	0.359	0.661	
Financial Behavior	B1	0.441	0.585	0.650
	B2	0.368	0.612	
	B3	0.512	0.557	
	B4	0.346	0.620	
	B5	0.269	0.650	
	B6	0.361	0.614	

The results from Table 6 illustrate that Cronbach's Alpha coefficient of all groups is > 0.6, which shows that the groups of the variables Financial Knowledge, Financial Attitude, and Financial Behavior are suitable to represent the overall variable financial literacy. However, in each group of variables, only a few scales score best (Correct Item-Total Correlation > 0.4). The remaining non-standard scales are omitted. In particular, the best scales for the Financial Literacy

variable are K5 and K6. The best scales for the Financial Attitude variable are A1, A2, A3, and A4. The best scales for the Financial Behavior variable are B1 and B3.

4.2. Group of scales using EFA

The scales selected as the best in Step 1 continue to be analyzed by EFA to verify convergence. The results show that the KMO coefficient reaches 0.726 (> 0.5), so the factor analysis is reasonable. Bartlett's test has statistical significance (Sig. = 0.000 < 0.05), showing that the observed variables in the population are correlated with each other. The total variance explained is 66.04% $> 50\%$, proving that eight separate scales in three groups can converge and reflect 66.04% of the change in all observations. The grouping of the scales is shown in the Rotated Component Matrix table. Because the scales chosen to perform the factor analysis are already the best (according to Cronbach's alpha reliability test), the grouping results ensure that the scales are in the correct representative group and all convergent. Factor loading coefficients are all very high, ranging from 0.643 to 0.871, showing the ability to measure the overall variables.

Table 7. Rotated Component Matrix

	Component		
	1	2	3
A3	0.812		
A2	0.795		
A1	0.761		
A4	0.643		
B1		0.871	
B3		0.797	
K5			0.849
K6			0.838

4.3. Measure and evaluate Financial Literacy

From the selected scales, we extract data to measure each aspect of financial literacy, attitudes, and behavior with the Mean of the scale in the group. From there, calculate the level of financial literacy as the average of the three aspects above. The means of the component variables and the total variable are presented in Table 8.

Table 8. Descriptive Statistics

	N	Minimum	Maximum	Mean	Std. Deviation
Financial Knowledge	1114	1.00	5.00	4.1481	1.0716
Financial Attitude	1114	1.00	5.00	4.3754	0.6211
Financial Behavior	1114	1.00	5.00	3.6346	0.8191
FL	1114	1.00	5.00	4.0528	0.5381

The average score in Table 8 shows that while Financial Behavior is still lower than Financial Attitude and Financial Literacy, all three aspects are generally at Good levels (an

average of about 3.4 to 4.2 on the Likert-5 scale, leading to good financial literacy among Vietnamese students - a good sign that the results have improved significantly compared to previous studies by Le Hoang Anh et al. (2018), Pham Thi Hoang Anh et al. (2021), Tran Thanh Thu et al. (2021). Furthermore, good financial literacy is also possible because the respondents of this study are mainly students from the major universities in Hanoi such as National Economics University, University of Science and Technology, Foreign Trade University. With high admission scores, students at these universities are expected to have higher qualifications and skills than the current youth average.

4.4. Identify factors affecting financial literacy

Comparing the difference in financial literacy by One_Way ANOVA with all demographic variables and digital transformation contextual variables shows that there is only a statistically significant difference in financial literacy among gender, majors, and use of SmartBanking and online investing.

Table 9. ANOVA

Criteria	Sig. of Levene Statistic in Homogeneity	Sig. of F in ANOVA	Sig. of Welch in Robust tests
Gender	0.061 (> 0.05)	0.021 (< 0.05)	
Age	0.162 (> 0.05)	0.553 (> 0.05)	
Education	0.000 (< 0.05)		0.000 (< 0.05)
Buying on e-commerce platform	0.456 (> 0.05)	0.645 (> 0.05)	
Using shopping apps and online payment	0.073 (> 0.05)	0.943 (> 0.05)	
Having bank account and Smart Banking	0.000 (< 0.05)		0.031 (< 0.05)
Investing online	0.003 (< 0.05)		0.000 (< 0.05)

Look at the difference in financial literacy between groups of students using the mean in the Descriptive Table or Multiple Comparison Table (Post Hoc test) provided in Table 10.

Table 10. Difference of FL in Gender

Gender		Mean Difference	Std. Error	Sig.
Male	Female	0.0909	0.0329	0.006
	Other	0.1074	0.2206	0.627
Female	Male	-0.0909	0.0329	0.006
	Other	0.0164	0.2201	0.941
Other	Male	-0.1074	0.2206	0.627
	Female	-0.0164	0.2201	0.941

Table 10 shows a statistically significant difference (95% confidence level) between the financial literacy of male and female students, showing that male students have higher levels of financial literacy than female students. This result reconfirms the existing opinion of

Chen and Volpe (2002), Eitel and Martin (2009), Nguyen Thi Hai Yen (2015), and Philippas & Avdoulas (2019).

Table 11. Difference of FL in Education

Education		Mean Difference	Std. Error	Sig.
Engineering	Language	0.1258	0.0539	0.020
	Economics	-0.0525	0.0393	0.182
	Other	0.2403	0.0604	0.000
Language	Engineering	-0.1258	0.0539	0.020
	Economics	-0.1783	0.0481	0.000
	Other	0.1145	0.0665	0.085
Economics	Engineering	0.0525	0.0393	0.182
	Language	0.1783	0.0481	0.000
	Other	0.2928	0.0553	0.000
Other	Engineering	-0.2403	0.0604	0.000
	Language	-0.1145	0.0665	0.085
	Economics	-0.2928	0.0553	0.000

The results in Table 11 show that students with engineering or economics majors have higher financial literacy than languages and other majors (99% and 95% confidence, respectively). For the two majors Engineering and Economics & Business Administration, the difference in financial literacy is not statistically significant. Thus, the education sector is still a factor that leads to the disparity in financial literacy. Given the importance of financial literacy, schools from secondary school upward need to be careful to integrate financial literacy teaching into the curriculum at levels ranging from simple to complex. At the university level, there is a need to include compulsory or elective subjects related to financial services, investments, and insurance in the educational program.

Table 12. Difference of FL in Having and using Smart Banking

		Mean Difference	Std. Error	Sig.
No bank account	Having a bank account, do not use Smart Banking	-0.2911	0.1186	0.014
	Having a bank account and use Smart Banking	-0.3887	0.1083	0.000
Having a bank account, do not use Smart Banking	No bank account	0.2911	0.1186	0.014
	Having a bank account and use Smart Banking	-0.0976	0.0540	0.071
Having a bank account and use Smart Banking	No bank account	0.3887	0.1083	0.000
	Having a bank account, do not use Smart Banking	0.0976	0.0540	0.071

All Sig values. shown in Table 12 have Sig. < 0.05 or < 0.1 indicates a statistically significant difference (95% or 90% confidence level) in financial literacy between groups of students that who have bank accounts and use Smart Banking have higher financial literacy than students who have bank accounts but do not use Smart Banking.

At the same time, students who have an account but do not use Smart Banking still have better financial literacy than unbanked students. Therefore, having a separate bank account (with or without independent income) and using the Smart Banking application together have a positive impact on financial literacy as the research team suggested. This can be explained by the convenience of having a bank account in everyday spending and the usefulness of Smart Banking in making payments, managing balance fluctuations, and saving online. Students who use Smart Banking regularly have the opportunity to control their own money (supported by their parents or self-employed) more conveniently and easily than students who do not have bank accounts or do not use Smart Banking.

Table 13. Difference of FL in Investing online

		Mean Difference	Std. Error	Sig.
Not interested in online investment	Interested, but not invested online yet	-0.1408	0.0346	0.000
	Interested and have online investment	-0.2782	0.0589	0.000
Interested, but not invested online yet	Not interested in online investment	0.1408	0.0346	0.000
	Interested and have online investment	-0.1374	0.0563	0.015
Interested and have online investment	Not interested in online investment	0.2782	0.0589	0.000
	Interested, but not invested online yet	0.1374	0.0563	0.015

With 99% and 95% confidence levels, Table 13 clearly shows the statistically significant difference that the financial literacy of interested students with online investing is better than interested students who have not yet made online investments. And students who are interested but have not done online investing before still have higher financial literacy than students who are not interested in online investing. Such a positive effect corresponds exactly to the expectations of the research group. It shows the impact of the wide availability of investment products on online platforms on the financial literacy of young people. These days, students can easily and quickly learn and register to open an investment account, make transactions, summarize balances, and transfer principal/interest on a smartphone or computer connected to the internet. Investing online, even with a limited amount of money, is a helpful experience for students to practice risk assessment, determine expected returns, and manage portfolios. These are all essential and at a higher level of personal financial literacy. In

addition, the online investment experience from the student days also creates the prerequisite for effective management of one's asset portfolio in the future. Over time, these assets accumulate more and more. So, if they are well managed and continue to be profitable within the allowable risk threshold, it will increase the value of a person's wealth.

5. Conclusion

Based on the concept and measurement of Financial literacy of the OECD (2013) and OECD (2022), the research group created and developed a questionnaire (adapted) to survey 1,114 students at universities in Hanoi. The data collected are processed through Cronbach's Alpha, EFA and One_Way ANOVA & Post Hoc Test. The obtained results show that Vietnamese students have good financial knowledge, financial attitude, financial behavior in particular and FL in general (according to the interval assessment of the Likert 5 scale). This is a significantly improved result compared to previous studies and is above the general FL level of the population living in Vietnam. Regarding the factors affecting students' FL in Vietnam, using this sample, the authors discovered four factors leading to the difference in FL between groups of students including: Gender, Education, Having a bank account and Using Smart Banking, Having an online investment. Accordingly, male students have higher than female students. Students in Engineering, Economics & Business Administrative majors have higher FL than those in Language and Other majors. Related to the digital transformation situation in Vietnam, the authors found that having bank accounts, using Smart Banking, having interest and making online investments have contributed to the increase in students' FL. These are new, valuable insights that represent another positive influence of the digital transformation in addition to the effect on business performance of enterprises and customer satisfaction (mentioned in many reports, and other studies).

The above results also provide a scientific basis for Vietnamese government's solutions to improve the financial literacy of young people and the resident population, promoting financial inclusion strategy. Accordingly, there is a need to create opportunities for equal access to FL education for both genders, and to supplement FL educational content in educational programs from high school to university, continue to promote cashless payments and create opportunities for individuals to conveniently access and use modern transaction methods and financial instruments at low cost.

Abstract

The study has completed the TAM technology acceptance model when researching the intention to use e-learning with selected external factors and examining the impact of these factors on the student's intention to use e-learning. pellets. The study uses a quantitative research method, in which the research model is tested with a survey data set of 789 students. The results of the analysis revealed that the information quality, experience of using computers, enjoyment, and belief in one's own abilities positively influence perceived usefulness and ease of use, and both. This perception has a positive influence on the attitude towards using e-learning. Besides, usage attitude is an important factor that positively affects the intention to use e-learning.

Keywords: *E-learning, TAM model, ICT, intention to use, NEU.*

1. Introduction

The continuous development of information and communication technology (ICT) has brought great strides to e-learning. The advantage of e-learning is to reduce the time and cost of learning (Muruthy & Yamin, 2017)¹. In addition, e-learning also allows access to necessary knowledge anytime, anywhere, not limited by geographical boundaries (Raspopovic et al., 2017). Besides, for students, the advantages of e-learning are more recognized in career development, academic achievement as well as social value (Divaris et al., 2008). Finally, e-learning meets the increasing needs of users to personalize learning,

¹ Muruthy, A. E., and Yamin, F. M., 2017. The perception and effectiveness of Learning Management System (LMS) usage among the Higher Education students. *Journal of Technology and Operations Management*, 12(1), 86-98

allowing users to access the knowledge they are interested in, adjust the speed of the learning, and so on (Huang and Chiu, 2015).

The e-learning system is more dependent on digital media and telecommunications, so there are limitations that can negatively affect user satisfaction. Support from universities and organizations is needed to help solve the difficulties of using e-learning by ensuring proper design before students/users reach it.

In developed countries, the advantages of e-learning can be further promoted due to the development of physical infrastructure. On the other hand, e-learning systems in developing countries have been partially or fully applied in the learning process, but the effect has not been commensurate (Tarhini et al., 2017). Most e-learning implementation projects fail partially or completely due to resistance from users (Minh & Anh, 2020). This shows that the problem lies in not understanding the factors affecting the adoption of e-learning (Salloum, 2019).

Besides, most of the previous studies have focused on examining the impact of specific factors on the adoption of e-learning. But those factors often vary from study to study depending on the individual and the context. In particular, during the period of the COVID-19 epidemic occurring, education and training work was almost entirely suspended. Facing this situation, many Vietnam's universities have implemented the application of e-learning systems to ensure uninterrupted learning. At the same time, the university introduced and applied the e-learning system, including learning management systems (LMS) and communication systems (Microsoft Teams), thereby ensuring the learning process continues. However, the implementation and application of the e-learning system at that time and later still faced many difficulties and inefficiencies. It is clear that developed countries have used and studied the factors affecting the intention to use e-learning early on, have found the causes, provided solutions, and implemented them to improve the intention to use e-learning. Therefore, studying students' intention to use e-learning in Vietnam is necessary. Furthermore, conducting this research is very important, especially in Vietnam, where the application of e-learning is still limited (Pham & Ho, 2020).

2. Literature Review and Theoretical Framework

To explore the above limitations, the main purpose of the study is (1) *to complete the technology acceptance model (TAM) when studying the intention to use e-learning with selected TAM's external factors* and (2) *to examine the impact of the above factors on student's intention to use e-learning*, a case study at the National Economics University. In addition, considering these factors will strengthen researchers' ability on this topic and improve e-learning adoption rates by strengthening based on cultural, social, and technical factors and related techniques to facilitate use. Furthermore, an understanding of these factors is expected to help educators and business managers identify the strengths and weaknesses of e-learning infrastructure and enhance user support intention to use e-learning.

Definition of e-learning

E-learning is defined as a teaching and learning method that fully or partially represents an educational model based on the use of electronic media and devices as a tool to increase the effectiveness of training and communication, and interaction while helping to accept new ways of perceiving and establishing learning (Krishnan & Hussin, 2017; Rhema, 2013).

TAM technology acceptance model

The Technology Acceptance Model (TAM) proposed by Davis (1985) has been used in various studies, and since then, it has become one of the important tools in academia, especially in the study of technology acceptance. Besides, in a recent analysis, this model was also proven to be more effective than other models when applied to studying technology acceptance in education.

According to this model, both perceived usefulness and perceived ease of use are influenced by external factors. Those two perceptions are used to predict users' attitudes towards technology use. The figure below illustrates the TAM model.

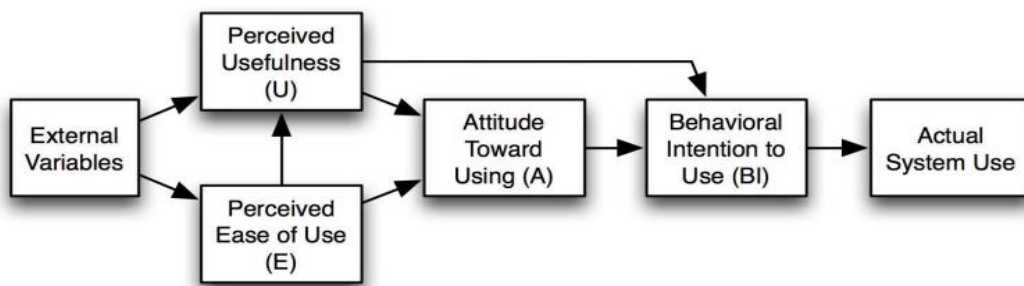

Figure 1. Technology acceptance model

Source: Davis (1985)

Technology acceptance model in predicting behavioral Intention using E-learning

The research review shows that the TAM model has been widely used and extended by many studies to evaluate and restructure the context of using e-learning. Two constructs of the TAM model (perceived usefulness and ease of use) have been applied to assess university students' acceptance of web-based courses (Selim, 2003). The results show that the usefulness and ease of use of the web-based course are proven to be the main determinants of the acceptance and use of the web-delivered course as an effective learning technology.

Abdullah and Ward (2016) identified 152 extrinsic factors by reviewing 107 articles published during the previous years. Their research results show that five factors such as *self-efficacy, subjective norms, enjoyment, computer anxiety, and prior experience* are considered to be the most used extrinsic factors. It has been found that the impact of the most widely used extrinsic factors is limited to the core beliefs of TAM, i.e. extrinsic factors affect only perceived usefulness and ease of use. Although the work of Abdullah and Ward (2016) has contributed significantly to the relevant rationale, their study did not include all relevant

research in the context of e-learning adoption and barriers. barriers to time and especially the development of technology in recent years. Therefore, this study aims to assess the influence of factors on students' intention to continue using e-learning based on the technology adoption model (TAM), applied to students at the University of National Economics.

Abdullah and Ward (2016) analyzed the previous studies using the TAM technology acceptance model in the use of e-learning. Research results show that there are only eight external factors (self-efficacy, subjective norm, enjoyment, system quality, content quality, knowledge quality, accessibility, and pleasure in using a computer) that have a relationship with TAM. Among the three influencing factors of the e-learning system, there are two factors that are system quality and content quality that will not affect students' intention to use e-learning because in the same research context at the university National Economics University, these two factors are the same for all students. The same goes for the "Elearning system Accessibility" factor (the extent to which users can easily access and use and extract information from the system). This is also a factor that will not change with students in the same university. The results identified five external factors that were chosen for the model.

Information quality (IQ)

Information quality refers to the issue that e-learning has new and updated knowledge useful for users' learning. In previous studies, there is a relationship between information quality and perceived usefulness, and perceived ease of use in the process of using e-learning (Jaber, 2016; Wongvilaisakul and Lekcharoen, 2015; Motaghian et al., 2013). Therefore, the following hypotheses are proposed:

H1a: Information quality (IQ) has a positive effect on the perceived usefulness (PU) of the e-learning system.

H1b: Information quality (IQ) has a positive effect on the perceived ease of use (PEU) of e-learning systems.

Prior experience (PE)

According to Abdullah and Ward (2016), prior experience is the most common factor when using the TAM model to predict e-learning acceptance. Previous literature also found evidence that prior experience influences perceived usefulness and perceived ease of use during e-learning use. Therefore, the following hypotheses are proposed:

H2a: Prior experience (PE) has a positive influence on the perceived usefulness (PU) of an e-learning system.

H2b: Prior experience (PE) has a positive effect on the perceived ease of use (PEU) of an e-learning system.

Subjective norm (SN)

Subjective norm is shown to have a strong relationship with the TAM model (Abdullah & Ward, 2016). Subjective norm is understood as an individual's perception that important people to that individual will influence whether that individual performs or does not perform a particular behavior (Fishbein & Ajzen, 1977).

In certain situations, there is a possibility that an individual may use a system (e.g. e-learning) to comply with the request of another (e.g. teacher, friend, parent, ...), instead of focusing on their personal feelings and beliefs (Davis, 1989). Previous studies have also shown that subjective norm has an influence on perceived usefulness in the process of using e-learning (Davis, 1989; Ajzen, 1991; Revyathi & Tselios, 2017). The following hypotheses are suggested:

H3a: Subjective norm (SN) has a positive influence on the perceived usefulness (PU) of the e-learning system.

H3b: Subjective norm (SN) has a positive influence on the perceived ease of use (PEU) of e-learning systems.

Enjoyment (ENJOY)

Enjoyment is defined as the extent to which a user enjoys using the information gathered from e-learning, regardless of factors such as computer performance.

To delve deeper into the adoption of e-learning, the study of user enjoyment plays an important role. Abdullah and Ward (2016) conducted a study showing that enjoyment significantly affects perceived usefulness and ease of use in the process of using e-learning. As enjoyment increases, so does the intention to use e-learning. From that, the following hypotheses are proposed:

H4a: Enjoyment (ENJOY) has a positive effect on the perceived usefulness (PU) of the e-learning system.

H4b: Enjoyment (ENJOY) has a positive effect on the perceived ease of use (PEU) of e-learning systems.

Self-efficacy (SE)

Self-efficacy is understood as an individual's belief in his or her ability to perform a particular task. Many studies show that self-efficacy is correlated with the perceived usefulness of e-learning (Chu et al., 2008). The following hypotheses are suggested:

H5a: Self-efficacy (SE) has a positive effect on the perceived usefulness (PU) of the e-learning system.

H5b: Self-efficacy (SE) has a positive effect on the perceived ease of use (PEU) of e-learning systems.

Perceived usefulness (PU)

Perceived usefulness refers to the extent to which individuals believe that using new technology can improve their job performance. Various empirical studies indicate that PU is the main determinant of the use of a particular technology.

An e-learning system can only be accepted by students when they perceive that its use will improve learning efficiency. Previous e-learning studies have shown that there is a significant positive correlation between perceived usefulness and behavioral intention to use e-learning. The following hypothesis is suggested:

H6: Perceived usefulness (PU) has a positive influence on attitude to use (ATT) e-learning system.

Perceived ease of use (PEU)

Perceived ease of use refers to how simple an individual feel when using a technological tool. Many studies show that perceived ease of use is positively correlated with behavioral intention to use, directly or indirectly. For e-learning, perceived ease of use refers to whether students find e-learning simple and easy to understand. From this, the following hypothesis is proposed:

H7: Perceived ease of use (PEU) has a positive influence on attitude towards using the e-learning system (ATT).

Attitude Towards Use (ATT)

Attitude refers to whether a person has positive or negative feelings about using e-learning. Many studies have shown that attitude has a direct influence on human behavioral intentions. So the following hypothesis is proposed:

H8: Attitude (ATT) has a positive influence on behavioral intention to use (INT) the e-learning system.

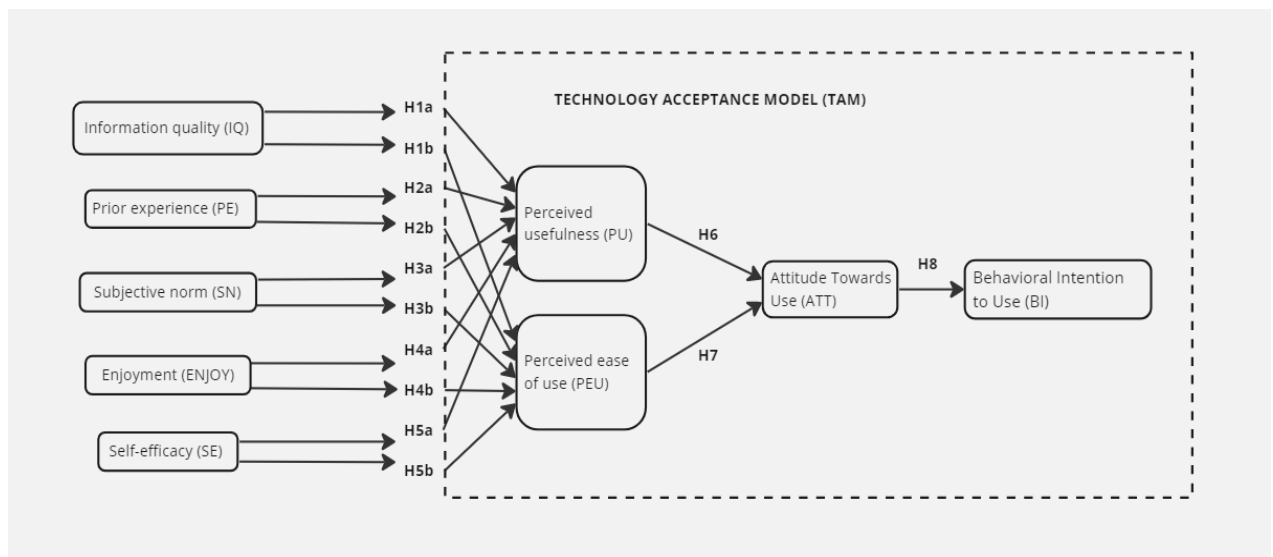

Figure 2. Research model and hypothesis

3. Method

The research team applied a quantitative method, based on primary data, collected through a survey of nearly 800 students of the National Economics University. After determining the factors for model building, research, and survey design with 32 questions, the survey was conducted in a narrow range to test the reliability and significance of the scale, then survey expansion. 789 valid questionnaires were collected and included in the analysis.

The scale prepared by the group is measured according to the Likert scale. The research team has built a scale with the specific observed variables as follows: The

information quality (IQ) scale is adjusted from the scale of Salloum & cs. (2019); The prior experience (PE) scale is adapted from the scale of Abdullah & Ward (2016); The subjective norm scale (SN) is adapted from the scale of Venkatesh & Davis (2000); The Enjoyment Scale (ENJOY) was adapted from the scale of Salloum et al. (2019); Scale of self-efficacy (SE) is adjusted from the scale of Bandura (1982); The perceived usefulness scale (PU) is adapted from the scale of Venkatesh & Davis (2000); Perceived ease of use (PEU) scale was adapted from the scale of Lee et al. (2009), Mohammadi (2015); The Attitude to Use Scale (ATT) was adapted from the scale of Masrom (2007), Sun et al. (2008); The Intent to Use Scale (INT) was adapted from the scale of Lee et al. (2009), Mohammadi (2015).

After the data is encrypted, SPSS 26 software will be used to test Cronbach's Alpha reliability coefficient, exploratory factor analysis (EFA), and correlation analysis. In which, the reliability coefficient helps to evaluate the reliability of the scale; exploratory factor analysis helps to evaluate convergent and discriminant values; Correlation analysis between the variables in the model to check the linear correlation between the dependent variable and the independent variable. The research team then uses regression analysis to test the hypotheses and draw conclusions. Finally, the research team used T-test and One-way ANOVA to test the differences in characteristics of the study sample.

4. Results

Descriptive statistics

The results obtained from the survey showed a large gender difference. Among 789 students participating in the survey, the female gender accounted for 73.9%, corresponding to 583 people while the male gender accounted for 26.1% with 206 people.

Scale reliability test results

The research team used Cronbach's Alpha coefficient to evaluate the reliability of each scale and performed exploratory factor analysis (EFA) to evaluate the convergent and discriminant value of these scales.

Cronbach's Alpha test shows that all observed variables have a total correlation coefficient greater than 0.3 and Cronbach's Alpha coefficient greater than 0.6. The results of evaluating the reliability of the scale by Cronbach's Alpha coefficient show that all the scales and observed variables are satisfactory. (Table 1)

The results of exploratory factor analysis EFA

For EFA exploratory factor analysis, KMO, and Bartlett tests are used to test the correlative relationship between variables and the fit of the factor analysis model, $0.5 < \text{KMO} < 1$, the factor analysis is fit. If this test is statistically significant ($\text{Sig} \leq 0.05$), then the observed variables are correlated with each other in the population (Hair, Anderson, Tatham, and William, 2006). Bartlett's test results have a KMO coefficient of 0.800, with the significance level $\text{sig} = 0.000 < 0.5$, showing that the observed variables are correlated with each other in the population, so the data used for analysis is completely appropriate.

Table 1. Results of testing the reliability of the scale

Factor	Number of observed variables	Cronbach's Alpha coefficient
Information Quality (IQ)	5	0,728
Prior Experience (PE)	2	0,830
Subjective Norm (SN)	2	0,920
Enjoyment (ENJOY)	5	0,755
Self-efficacy (SE)	3	0,706
Perceived Usefulness (PU)	4	0,832
Perceived Ease of Use (PEU)	4	0,767
Attitude (ATT)	3	0,841
Intention to Use (INT)	4	0,785

Correlation analysis results

Sig Pearson correlation between variables is less than 0.05. Thus, there is a linear relationship between the independent variables and the dependent variables. The correlation coefficient r between the variables also has a value of $r > 0$ showing that the variables have a positive relationship with each other. (Table 2)

Table 2. Results of Pearson correlation analysis among all variables

	IQ	PE	SN	ENJOY	SE	PU	PEU	ATT	INT
IQ									
PE	.339**								
SN	.406**	.335**							
ENJOY	.640**	.570**	.620**						
SE	.334**	.780**	.419**	.576**					
PU	.632**	.413**	.542**	.898**	.491**				
PEU	.900**	.254**	.356**	.497**	.304**	.475**			
ATT	.367**	.327**	.308**	.400**	.370**	.346**	.332**		
INT	.486**	.377**	.846**	.643**	.517**	.627**	.449**	.377**	

Note: (**) significant correlation at 0.01 level (1%); (*) the correlation is significant at the 0.05 level (5%)

Results of regression analysis and hypothesis testing

Since the model has many intermediate variables, the number of regressions to run will correspond to the number of variables that have a dependent role in the model. Thus, it is necessary to run four regressions. The sample regression model is written with the normalized regression coefficients as follows: (Figure 3)

$$PU = 0.106 + 0.922*ENJOY + 0.375*IQ + 0.233*PE + 0.123*SE$$

$$PEU = 0.202 + 0.988*ENJOY + 0.330*IQ + 0.172*PE + 0.136*SE$$

$$ATT = 2.421 + 0.243*PU + 0.216*PEU$$

$$INT = 2.242 + 0.377*ATT$$

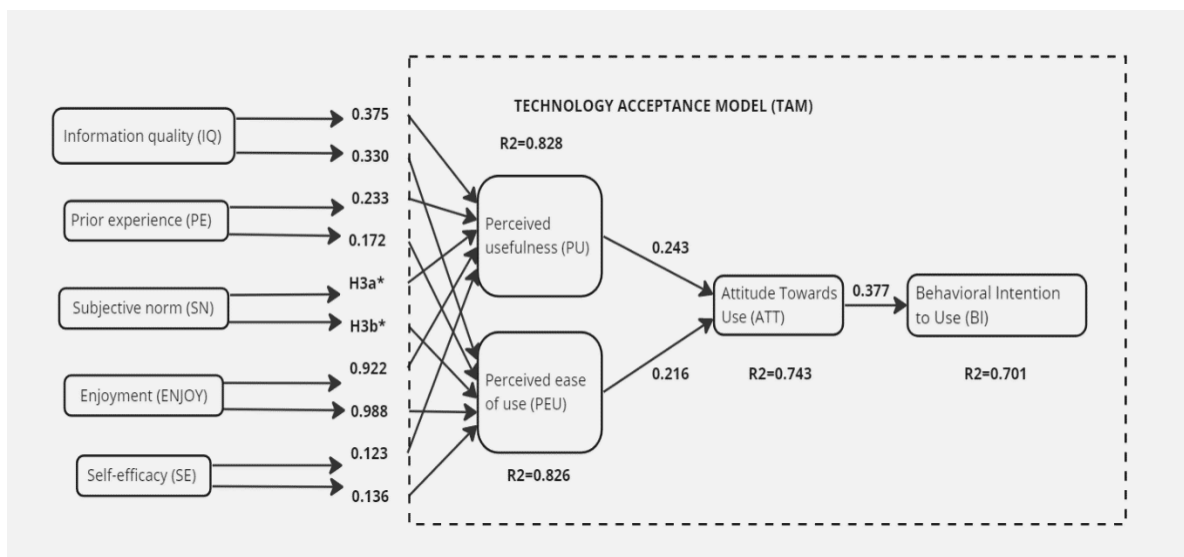

Figure 3. Results of regression analysis and hypothesis testing (*sig > 0.05)

Result of the difference test

Gender: Levene's sig value is 0.416 > 0.05, we can conclude that the variances of the groups of values are identical. Using the sig results in the ANOVA table, the sig value is 0.636 > 0.05, thus concluding that there is no difference in behavioral intention to use different e-learning between male and female genders.

Years of study: Levene's sig value is 0.115 > 0.05, we can conclude that the variances of the groups of values are identical. Using the sig results in the ANOVA table, the sig value is 0.079 > 0.05, thus concluding that there is no difference in behavioral intention to use different e-learning among students by year study differently.

Thus, through the analysis results, we can confirm that the results of the initial hypotheses are as follows:

Hypothesis	Results
H1a: Information quality (IQ) has a positive effect on the perceived usefulness (PU) of the e-learning system.	Supported
H1b: Information quality (IQ) has a positive effect on the perceived ease of use (PEU) of e-learning systems.	Supported
H2a: Prior experience (PE) has a positive influence on the perceived usefulness (PU) of an e-learning system.	Supported
H2b: Prior experience (PE) has a positive effect on the perceived ease of use (PEU) of an e-learning system.	Supported
H3a: Subjective norm (SN) has a positive influence on the perceived usefulness (PU) of the e-learning system.	Not supported
H3b: Subjective norm (SN) has a positive influence on the perceived ease of use (PEU) of e-learning systems.	Not supported

Hypothesis	Results
H4a: Enjoyment (ENJOY) has a positive effect on the perceived usefulness (PU) of the e-learning system.	Supported
H4b: Enjoyment (ENJOY) has a positive effect on the perceived ease of use (PEU) of e-learning systems.	Supported
H5a: Self-efficacy (SE) has a positive effect on the perceived usefulness (PU) of the e-learning system.	Supported
H5b: Self-efficacy (SE) has a positive effect on the perceived ease of use (PEU) of e-learning systems.	Supported
H6: Perceived usefulness (PU) has a positive influence on the attitude (ATT) e-learning system.	Supported
H7: Perceived ease of use (PEU) has a positive influence on attitude towards using the e-learning system (ATT).	Supported
H8: Attitude (ATT) has a positive influence on behavioral intention to use (INT) the e-learning system.	Supported

5. Discussion and Conclusion

The obtained results show that information quality has a positive effect on the perceived usefulness and the perceived ease of use of the e-learning system, similar to the results of Thai Kim Phung et al. (2016). This indicates that when the information quality of the e-learning system is guaranteed to be up-to-date and clear, students believe that using e-learning is useful for their learning and do not feel difficult to use. The above results also show that prior experience and enjoyment positively affect students' perceived usefulness and ease of use when using e-learning. Therefore, as students have more experience with the internet and electronic devices and show an open tendency to interact naturally with the e-learning system, the perceived usefulness of the system inevitably increases and usage is less supposed to be more complicated. Self-efficacy was also found to have a positive effect on perceived usefulness and ease of use. This means that e-learning is said to be more useful and easy to use when students believe that they can perform the tasks on the system to achieve the desired results.

Subjective norm was the only factor shown to have no impact on perceived usefulness and perceived ease of use. Research shows that nowadays e-learning has become an integral part of students' formal learning process, so students' perceptions and attitudes are not much affected by the judgments of people around them about this system. This result disagrees with the results observed in the previous study by Kimathi and Yi Zhang (2019) at the University of Dar es Salaam, Tanzania. This difference can be explained by the difference in context when our research was conducted after the Covid 19 epidemic, which made e-learning an indispensable and accepted part widely in the educational environment.

Regarding the components of TAM, the results show that perceived usefulness and perceived ease of use have a positive influence on the attitude toward the use of the e-learning system. This result agrees with the original theoretical foundation of TAM and is quite similar to the research results of Le Hieu Hoc and Dao Trung Kien (2016) when studying the factors affecting the intention to use e- student learning, a case study at Hanoi University of Science and Technology. So, when students believe that the e-learning system is useful and find the system user-friendly, their attitudes inevitably become better. Moreover, the study clearly shows that students' attitude has a significant positive influence on behavioral intention to use e-learning. When students express a positive attitude towards using e-learning, their behavioral intention increases. Using these factors, stakeholders can design and adjust the e-learning system to increase the motivation to use e-learning for learning purposes of students. Recognizing these factors can also help improve the capacity of researchers and improve the rate of intention to use e-learning in the Vietnamese context by looking at the factors studied in this study. this study.

The study reinforces the application of the TAM model along with additional factors to the model in the Vietnamese context. Research results also help to enhance and deepen the understanding of external factors and provide useful suggestions for policymakers, experts, developers, and designers in the application of effective e-learning systems.

Although the results of the study have played a certain role in perfecting the TAM model and describing the intention to use e-learning of students at the National Economics University, it has also set some limits. First, the subjects of the study were university students and did not consider the opinions of the instructors, and if the faculty responses were considered, comparisons between analyzes could be made. of instructors and students. Further research should consider this argument. Second, use patterns and determine user opinions and intentions for a single point in time. Therefore, it is advisable to do more research using follow-up surveys over a longer period of time as it is possible that individuals' perceptions and preferences will change as they gain more experience over time.

Abstract

This paper's objective is to analyze and assess the impact of digital transformation on electronic payment usage in Vietnam. The study uses the method of analyzing and testing the linear structural model (SEM) on SmartPLS 4.0 from 652 observations collected through surveys of businesses and consumers in urban and rural areas of Vietnam. After six months of collecting and processing data, the analysis indicates that factors of digital transformation, which are the Quality of Digital Infrastructure and Government Support, influence electrical payment usage. Although these two factors do not directly affect the behavior, they only affect mediately through the variables Usage Intention, Expected Efficiency, Expected Effort, Payment Intermediaries, Security, and Social Influence. The strongest median variable is Security, which has a direct effect on Usage behavior, and following Security is Payment Intermediaries. Therefore, the study wants to indicate aspects of Digital Transformation that the Government and administrators should pay attention to promote non-cash payment.

Keywords: *digital transformation, usage behavior, electrical payments, government support, infrastructure quality.*

1. Introduction

In recent years, the development of Digital Transformation in Vietnam has made great strides. The rapid growth of digital transformation has innovated all fields. Especially, according to statistics from the Payment Department of the Vietnam State Bank, in the first 11 months of 2022, non-cash payment transactions increased by 85.6% in quantity and

31.39% in value compared to the first 11 months of 2021; In addition, the total number of activated e-wallets across the country increased by 10.37% in the first four months of 2022.

Contributing to that successful transition is impossible not to mention government support and the digital infrastructure. New technologies such as AI and big data have been applied in many fields, especially banking, and finance. Besides, it is indispensable for the Government's attention to development orientation and legal framework building. It matters that technology goes first and management follows. Governance is not only based on the legal system to ensure security; but also policies to maintain and encourage the growth of e-payments, such as business, user support and contribute to solving difficulties in production and business, ensuring social security.

This is the era of digital transformation but authors found that there have been few studies on e-payments under the impact of digital transformation, especially in Vietnam. Therefore, in this research, the authors will look at two main aspects: Government support and Infrastructure quality. In addition, there are many social aspects that previous studies have not touched on. Thus, the research team focuses on illuminating the impact of Digital Transformation on Vietnamese people's behavior in using electronic payments based on direct and indirect relationships. The study uses qualitative and quantitative methods following the PLS-SEM model. The structure of the research paper consists of 5 parts: 1 - Introduction, 2 - Literature review and theoretical framework, 3 - Research method, 4 - Results and discussion, and 5 - Conclusion and policy implication.

2. Literature review and Theoretical framework

2.1. Studies on the intention and behavior of using electronic payments

Electronic payment is defined by Kalakota & Whinston (1996) as any form of money transfer made through electronic devices. With this payment method, users can transfer, deposit, and withdraw money from their accounts easier and faster than using cash. According to Yu et al. (2002), there are currently four major categories of electronic payment systems: (1) online credit card payment, (2) electronic cash, (3) electronic checks, and (4) small payments.

The behavior of using technology can be understood as the totality of actions and the process of realizing the need until deciding to consume and use any technology. When studying usage behavior, intention to use is currently the primary factor studied to predict the usability and behavior of using a product, especially new technology products.

Research papers on electronic payment are numerous and have appeared early since the 2000s, in which the TAM model is commonly used. However, recent studies prefer the UTAUT model, which has been applied more and proven its superiority; in particular, Judani & Sfenrianto (2015) based on the UTAUT model to build a Model of Factors Influencing Consumers' Intention To Use E-payment System in Indonesia, and Wei et al. (2021) surveyed 295 users to evaluate the Young Generation's Mobile Payment Adoption Behavior in Taiwan. Both of these studies believe it is necessary to expand the scope and research subjects to have a broader view regarding the factors affecting the behavior of using electronic payments.

Most studies on the usage of new technology in Vietnam use the TAM model. Dao My Hang et al. (2018), when finding factors affecting the decision to use fintech services in payment activities of individual customers in Vietnam, suggest that banks should improve their technology infrastructure. However, the study only includes motivational factors, so further studies should also focus on objective factors such as social norms. While Pham Mai Khanh et al. (2021) found a new factor, Payment Intermediary, which was added after in-depth interviews with several customers using electronic payments. In the results, Payment Intermediary and Subjective Norm are tested to have the most impact on Attitude to use.

Studies using the UTAUT model in Vietnam, for instance Nguyen Duy Thanh and Cao Hao Thi & Nguyen Duy Thanh (2011) and Dao Thu Huong (2019). Nguyen Duy Thanh and Cao Hao Thi have added Legal Factors, which is a new and less noticed variable when researching consumer behavior. 24.76% of those surveyed were not aware of legal factors because they thought it was a factor in the macro scope. This shows that legal factors related to e-banking and electronic transactions have not been paying much attention in Vietnam. Similar to Dao My Hang et al. (2018) Nguyen Duy Thanh and Cao Hao Thi proposed that banks should pay more attention to technology infrastructure, especially security.

2.2. Studies on the impact of digital transformation

According to the Ministry of Information and Communications, digital transformation is the procedure of total and comprehensive change of individuals and organizations in the way of living, working, and production methods based on digital technologies. There have been many research articles on the impact of digital transformation, in which topics related to the influence of digital transformation on changing consumer behavior are of the most focus. Digital transformation mainly affects consumer behavior by changing methods for communicating, finding, and exchanging information about products and services, as well as buying and consuming (Hennig-Thurau et al., 2010). Gensler et al. (2017) believe that the current trend is online shopping since with this type of shopping consumers can easily search and compare products over the internet. Similarly, the study of 3 authors Demmers, Weltevreden, and van Dolen (2020) has described this change in user behavior in detail, shopping is increasingly influenced by digital advertising and ease of shopping in digital markets, especially e-commerce sites. Besides affecting consumers, digital transformation also affects business operations and marketing. Firms have adopted technology in how and where they sell products and services; they also apply technology in communicating with users. As a result, a new business model - the digital business model - has emerged.

There are also research papers in Vietnam on the impact of digital transformation; Pham Thuy Hong (2020) has shown that because of the effect of the digital economy, consumers' shopping behavior has visibly changed. Digital technology has facilitated maximizing user benefits, increasing experience, and participating in solving businesses' and customers' problems. Similarly, there are many research articles depicting the impact of digital transformation on internal enterprises, such as Nguyen Hong Minh (2020), Pham Huy Giao (2020), Vu Trong Nghia (2021), Vo Huu Hoa (2021). Most of these studies illustrate the current state of digital transformation in businesses, thereby pointing out challenges and suggesting more effective digital transformation solutions for these businesses.

2.3. Foundational theories

The Unified Theory of Acceptance and Use of Technology (UTAUT) was developed by V. Venkatesh, M.G. Morris, and F.D. Davis (2003). They argued that researchers faced numerous similar models proposed by multiple theories and noted that they “picked and chose” models from models or chose a “preferred model,” with the result that other models were largely ignored. Thus, they synthesized the proposals made by different acceptance models, including TRA, TAM, TPB, C-TAM-TPB, MM, MPCU, SCT, and IDT) and proposed the Unified Theory of Acceptance and Use of Technology (UTAUT).

UTAUT includes four main factors: Performance Expectancy; Effort Expectancy; Social Influence; Facilitating Conditions. Another significant difference between UTAUT and its predecessors is that UTAUT proposed four moderating factors (i.e., gender, age, experience, and voluntariness of use) to boost the model’s predictive ability.

The superiority of the UTAUT model has been demonstrated in many studies, such as Foon & Fah’s study (2011), where they observed the intention to use internet banking services among 200 customers with accounts at Malaysian banks. The results showed that Performance Expectancy, Effort Expectancy, Social Influence, and Facilitating Conditions, all played crucial roles in influencing the intention to use internet banking. And their results also showed that their research model could explain an average of 56% of changes in intention to use the services. Due to the superiority of the UTAUT model over other models, the research team decided to rely primarily on UTAUT to construct their research model.

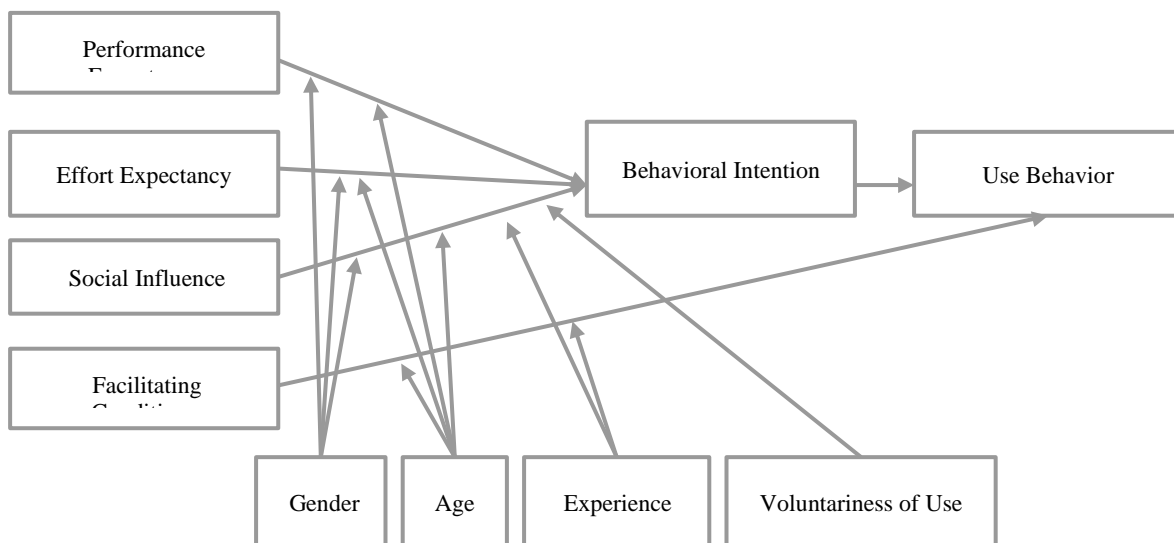

Figure 1. Unified Theory of Acceptance and Use of Technology Model

Source: Venkatesh et al. (2003).

2.4. Hypotheses and research model

Based on Venkatesh et al. (2003) and Foon & Fah (2011), the research team mostly used the hypotheses of the UTAUT model. However, to avoid unneeded and suit the research objectives, we removed the Facilitating Conditions hypothesis and variables. To explain this, we must look at the definition of Facilitating Conditions according to Venkatesh et al. (2003): Facilitating Conditions are the degree to which an individual has the necessary organizational and infrastructure support to use a technology system and the organizations or technological infrastructure operate to enhance and eliminate barriers to use. Meanwhile, the research objective focused on the intention and behavior of using electronic payments in a specific facilitating condition - digital transformation.

2.4.1. The Intention to Use electronic payments, Performance Expectancy, Effort Expectancy, Social Influence.

Venkatesh et al. (2003) concluded that behavioral intention strongly influences technology use. With electronic payments, Raza et al. (2018) research result confirmed that the intention to use electronic payments has an immense impact on the actual use. Pham et al. (2022), when studying the factors affecting the intention to use online banking, also agreed that intention positively affects the decision. Thereby, the research team proposed the hypothesis:

H1: The Intention to Use has a positive impact on Usage Behavior

2.4.2. Performance Expectancy

If customers have high expectations and see the usefulness of e-payment, they intend to use and continue to use e-payment; thus, the research team believes that Performance Expectancy positively impacts the intention to use payment service. There have been many foreign studies demonstrating that Performance Expectancy can explain the intention to use technology (Alalwan, 2015); and Performance Expectancy has also been shown to have a positive effect on the intention to use online payment services in Vietnam (Ha Nam Khanh Giao and Vo Van Linh, 2011; Tran Thi Khanh Tam, 2018). From that, the authors hypothesized:

H2: Performance Expectancy has a positive impact on the Intention to Use

2.4.3. Effort Expectancy

Effort Expectancy is proportional to the perceived ease of use of technology products and services (Ha Nam Khanh Giao and Vo Van Linh, 2011; Tran Thi Khanh Tam, 2018). Many research results show that Effort Expectancy not only has a positive impact on user intention but also has an indirect effect on increasing customer satisfaction, thereby affecting intention (Priya and Vikas Gandhi et al., 2018).

H3a: Effort Expectancy has a positive impact on the Intention to Use

There are several studies on the impact of Effort Expectancy on Performance Expectancy, such as Venkatesh and Davis' study (2000). They argued that when users find technology easy to use, they will evaluate it as helpful and intend to use it more. The final results of this study proved this point: Effort Expectancy had a direct and significant impact on Performance Expectancy. Therefore, the research team proposed the following hypothesis:

H3b: Effort Expectancy has a positive impact on Performance Expectancy

2.4.4. Social Influence.

Social Influence is defined as how a customer perceives and will use an electronic transaction service because of the influence of others around them. According to Philip Kotler, consumer buying behavior is strongly influenced by social characteristics. Research by Do Thi Huong et al. (2021) suggests that Social Influence positively correlated to the intention to use electronic payment at supermarkets in Hanoi. Moreover, it is also one of the two factors having the most significant impact on the intention to use electronic payments at supermarkets in Hanoi. As a result, the research team came up with hypothesis H4 regarding Social Influence:

H4: Social Influence has a positive impact on the Intention to Use

2.4.5. Security

Al-Dala'in et al. (2009) focused on finding the influence of reliability and security factors on user behavior in online services. The results of Luo et al. (2010) showed that both reliability and security factors significantly impact user behavior, which is similar to the findings of.

H5: Security has a positive impact on Usage Behavior.

2.4.6. Payment intermediaries:

Payment intermediaries play a role as intermediaries connecting businesses and customers and are the only party in e-commerce transactions that can verify the identity and location of sellers. And according to Nguyen Hong Quan (2021), e-commerce support policies include policy mechanisms, rules, and regulations of sellers or e-commerce service providers aimed at committing and ensuring consumers their obligations and responsibilities towards consumers who have used or are using e-commerce services to purchase goods through websites. Therefore, payment intermediaries have also been considered a vital factor influencing customer intentions and acceptance behaviors toward new technologies and features.

H6: Payment intermediaries has a positive impact on the Intention to Use

2.4.6. Digital transformation

➤ Government Support

In this study, Government support can be defined as the development of decisions and policies to promote the growth of Digital Transformation while protecting the rights and safety of society.

In Vietnam, decision 1813/QĐ-TTg 2021 approved the scheme on "The project of developing non-cash payment in Vietnam from 2021 to 2025". The project aims to promote electronic payments in the government sector and public administrative services. It strengthens the connection between payment service providers and payment intermediaries

with the Vietnam National Public Service Portal, the Electronic one-stop system of ministries, branches, localities, and hence facilitating electronic payment for fees, charges, payments of electricity bills, water, tuition, hospital fees, and so on. The convenience of using electronic payment services, therefore, increases significantly. Also, this could make people feel more comfortable using these services and enhance their usability.

H7a: Government support has a positive influence on Performance Expectancy

Furthermore, Dasgupta et al. (1999) argue that supportive government policies could improve the ease of use of e-services, facilitate people's access to e-services, and gain benefits through these services.

H7b: Government support has a positive influence on Effort Expectancy

In addition, citizens' trust in the government reflects the effectiveness of policies. Ergo, it can be seen whether the government has a positive or negative impact on the influence of society. According to Miller and Listhaug (1990), "Society's trust in government reflects judgments about whether government agencies and political organizations are functioning according to societal expectations. People's expectations of how the government works include: fairness, equality, honesty, effectiveness, efficiency, and meeting the needs of society."

H7c: Government support has a positive influence on Social Influence

Besides, the Vietnam Law on Cyber Information Security 2015 (No. 86/2015/QH13) has been enacted based on the experiences of other developed countries: the US, Europe, Japan, China, and many foreign organizations and enterprises. According to the report by Mr. Nguyen Phong Nha, Vietnam Deputy Director General in charge of the Department of Telecommunications, in 2021, the Department processed nearly 1.1 million SIMs with signs of improper subscriber information; blocked more than 78 million calls with signs of fraud; handle 227 thousand subscribers who spread spam calls.

H7d: Government support has a positive influence on Security

Moreover, Circular 23 shows the issue of great concern about payment intermediaries. Nguyen Hong Quan (2021) also pointed out that policy factors in the online payment environment are key to influencing user behavior. This factor relates to the regulations, commitments, and guarantees of payment intermediaries under the protection and control of the Government. Therefore, the authors proposed hypotheses:

H7e: Government support has a positive influence on Payment Intermediaries

➤ **Quality of Digital Infrastructure**

According to the Minister of the Ministry of Information and Communications, the Authority of Information Technology Application, considers digital infrastructure as a crucial and essential component for connecting, establishing, and maintaining the flow of data for the digital economy and society. This includes both physical infrastructure

(broadband telecommunications, data centers) and soft infrastructure (cloud computing, IoT connectivity) at high speeds and bandwidths to meet all the demands of the digital economy and society.

A United Nations Industrial Development Organization (UNIDO) report states that the Quality of Digital Infrastructure can help consumers make informed choices and help encourage businesses and industries to innovate in technology and organizational methods.

H8a: Quality of Digital Infrastructure has a positive influence on Performance Expectancy

In Bui Nhat Vuong's study (2021), it was also suggested that the development of technology, process improvements, and increased features help to support users in easy operation and utilization of technology services. It can be seen that the quality of digital infrastructure is the foundation upon which financial companies can deploy electronic payment services and provide diverse, user-friendly, and convenient electronic payment products. Based on this, the group puts forward the hypothesis:

H8b: Quality of Digital Infrastructure has a positive influence on Effort Expectancy

Moreover, the better the quality of infrastructure meets the needs, the more satisfied people will be and the more they will share with those around them. This is illustrated by the level of access to infrastructure such as the internet (the proportion of internet users in Vietnam accounts for over 70% of the population) and the percentage of internet users shopping online (88% in 2020, compared to 77% in 2019).

H8c: Quality of Digital Infrastructure has a positive influence on Social Influence

Additionally, according to Laukkanen and Lauronen (2005), individuals often have concerns about the security of personal information transmitted via mobile devices and applications, as well as connectivity risks (Black et al., 2001) and private issues (Kuisma et al., 2007). Therefore, it can be determined that a well-developed digital infrastructure plays a significant role in providing connectivity in payment transactions to avoid problems such as internet connection failures, system and maintenance failures, and errors due to human factors... to minimize manipulation, save time as well as prevent confusion and reduce the risk of leakage.

H8d: Quality of Digital Infrastructure has a positive influence on Security

Research by Yao et al. (2018) indicates that the rapid development of information technology and the Internet has changed consumer payment patterns. Consumers increasingly prefer online shopping and electronic payments. But credit risk is a major obstacle in the development of the e-commerce market (Yan and Chang, 2007), so payment intermediaries were born as a way to solve the problems of trust and security of financial transactions between people buy and sell (Cheng et al., 2017, similar to Wu (2020)). From the above arguments, the authors came up with the following hypotheses:

H8e: Quality of Digital Infrastructure has a positive influence on Payment Intermediaries

2.5. Research model

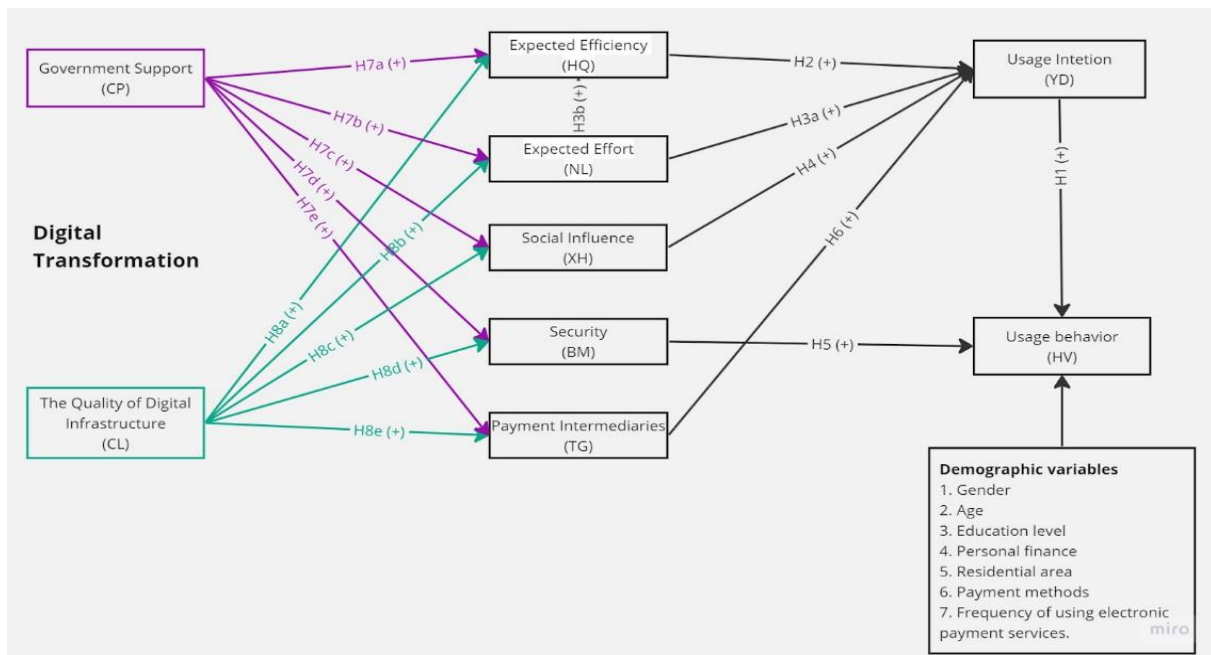

Figure 2. Proposed research model

Source: Authors' compilations based on Venkatesh et al, 2003

3. Method

The authors use research data including both primary and secondary data.

3.1. Qualitative research methodology

According to the result's in-depth interviews with 20 presidents and representatives of shops and businesses, the team also concluded on factors of the article: Government Support, Efficiency, Effort, and Payment Intermediaries variables have a positive impact on people's use of e-commerce; Infrastructure Quality, Security, and Social Influence have an unclear impact on intention to use e-commerce; survey subjects at different ages and regions also have dissimilar thoughts regard using e-commerce.

3.2. Quantitative Methodology

Our goal is to identify and measure the impact of factors affecting the behavior of Vietnamese people in using e-payment. The authors found that measuring observed variables by using Likert scale is the most optimal. This study was conducted in Vietnam based on 7 big variables and 37 observed variables; with the targeted object being people living across the country for more than six months (from August 5, 2022, to February 15, 2023); the scope allowed for online and direct surveys via questionnaires in the northern region.

In this study, the collected data has been checked, cleaned, stored, and analyzed using Excel, SPSS 20.0, and SmartPLS 4.0 software. Then, the Partial Least Squares Structural Equation Modeling (PLS-SEM) (Ha Nam Khanh Giao & Bui Nhat Vuong, 2019) will be

used to evaluate and conclude the relationships and intermediate roles of variables in the intention and behavior of using electronic payments by people in the context of the study.

4. Results

4.1. Descriptive statistical analysis

After distributing the survey questionnaire, the research team filtered the error results and obtained 652 valid votes, meeting the minimum number of requirements. The result, men accounted for 29.8%; women accounted for 70.2%; the proportion of people under 18 years old is 3.5%; the age group 18-25 accounts for 62.1%, the age group 25-30 accounts for 18.25%, the age group 30-40 accounts for 8.7% and the age group over 40 accounting for 7.4%; the proportion of people living in urban areas (Hanoi City, Hai Phong City) accounts for 56.5%, and people living in non-urban provinces (Hung Yen, Lao Cai, Thai Nguyen, Bac Ninh, etc.) accounted for 44.5%.

The survey shows Internet banking is the most used service by 82.8% of participants, and the least used service is for Online investment transactions with 11.3%. The results of the survey show survey participants are using e-payment quite frequently with 48.3% of participants using e-payment daily.

4.2. Testing measurement model

To assess the measurement model, the authors focused on the indicators: quality of observed variables, reliability, convergence, and the discriminability of the scales. Evaluating the quality of the observed variables: According to the results of Figure 3, all loading coefficients of all observed variables are greater than 0.708, satisfying the quality according to Hair et al. (2014) since $(0,708)^2 = 0,5$, which means latent variables have explained 50% of the variation of the observed variable. Therefore, the scale has good internal consistency reliability.

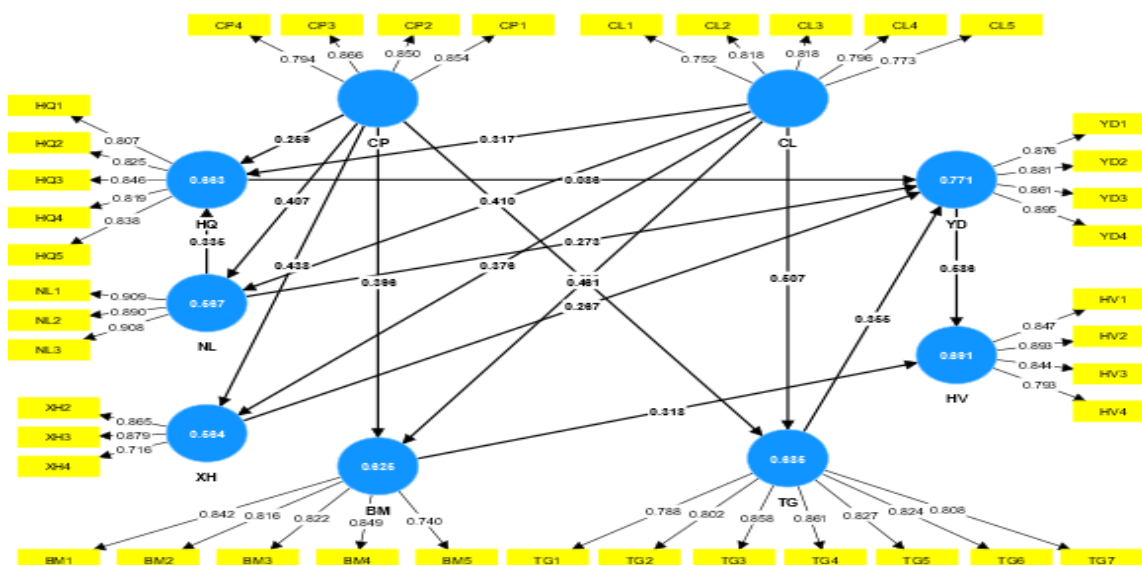

Figure 3. Results of the analysis of the quality of the observed variables.

Source: Results from SmartPLS analysis, 2023 data collected by the research team.

4.2.1. Evaluate the reliability and convergence of the scale:

From table 1, it is shown that all factors have Cronbach Alpha coefficients, Composite Reliability CR, and AVE coefficients that satisfy the combined reliability conditions that DeVellis (2012), Bagozzi & Yi (1988), and Hock & Ringle (2010) released.

Table 1. Reliability results and convergence value of the scale

Scale	Number of observed variables	Outer Loading	Cronbach's Alpha	Composite reliability (rho_a)	Composite reliability (rho_c)	Average Variance Extracted (AVE)
Security	5	(0,740-0,849)	0,873	0,874	0,908	0,664
Quality of Digital infrastructure	5	(0,752-0,818)	0,851	0,852	0,893	0,627
Government Support	4	(0,794-0,866)	0,863	0,864	0,906	0,708
Performance Expectancy	5	(0,807-0,846)	0,884	0,885	0,915	0,684
Effort Expectancy	3	(0,890-0,909)	0,873	0,874	0,929	0,814
Payment Intermediary	7	(0,788-0,861)	0,887	0,888	0,937	0,679
Social Influence	3	(0,716-0,879)	0,921	0,922	0,863	0,678
Intention to Use	4	(0,861-0,895)	0,792	0,793	0,909	0,772
Usage Behavior	4	(0,793-0,893)	0,901	0,902	0,931	0,714

Source: Results from SmartPLS analysis, 2023 data collected by the research team

4.2.2. Testing the discriminant value of the scale

From Table 2, it is shown that all factors have the discrimination validity that satisfies the combined reliability conditions that Henseler et al. (2015) released (with the value is below 0.9, the discrimination will be valid). Therefore, it is satisfied to perform the next test.

Table 2. HTMT

	BM	CL	CP	HQ	HV	NL	TG	XH
BM								
CL	0,855							
CP	0,826	0,815						
HQ	0,750	0,842	0,817					
HV	0,806	0,765	0,738	0,767				
NL	0,723	0,799	0,794	0,829	0,785			
TG	0,846	0,879	0,834	0,835	0,827	0,830		
XH	0,820	0,841	0,863	0,813	0,845	0,806	0,829	
YD	0,741	0,770	0,777	0,825	0,897	0,877	0,892	0,899

Source: Results from SmartPLS analysis, 2023 data collected by the research team

4.3. Testing structural model

4.3.1. Structural model analysis results

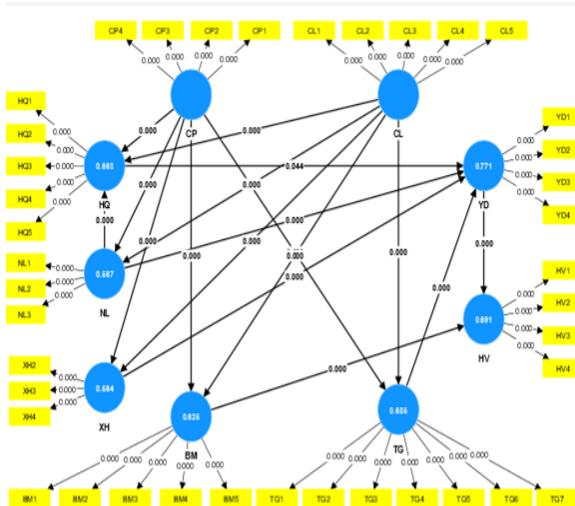

Figure 4a. Results of P value

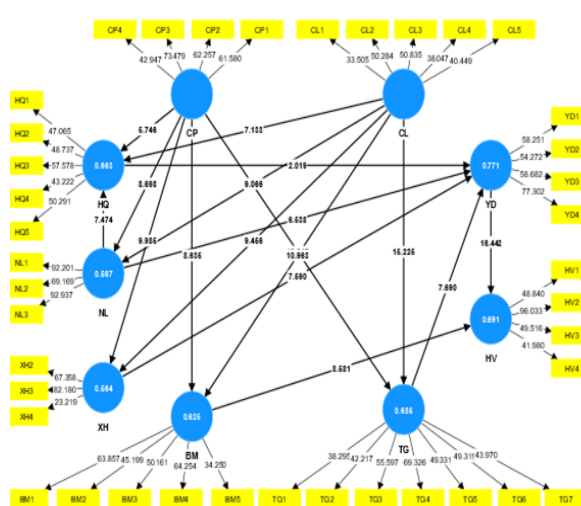

Figure 4b. Results of T test

Source: Results from SmartPLS analysis, 2023 data collected by the research team.

After testing the model's outer loading results, the research team continues to test T value in the figure below. The T values depicted in Figure 4b of the variables are all greater than 1.96, and all the P values (Figure 4a) are smaller than 0.05. This means the authors' hypotheses are correct

4.3.2. Testing multicollinearity problem:

To test for multicollinearity in the model, the team analyzed the variance inflation factor (VIF). According to Hair et al. (2019) $VIF < 3$ to reduce multicollinearity. Team's analysis showed that all the VIFs of the observed variables are between 1,337 and 2,886 that are smaller than 3, which means there may be no multicollinearity.

4.3.3. Testing relationships:

Before testing the level of impact between the relationships of the variables, the authors checked the P value in section 4.3.1, showing that these values are statistically significant.

➤ **The explanatory level of the independent variable for the dependency (R squared):**

Table 3. R-square, R-square adjusted

	BM	CL	CP	HQ	NL	TG	XH
R-square	0,564	0,625	0,663	0,691	0,567	0,771	0,685
R-square adjusted	0,562	0,664	0,662	0,690	0,566	0,769	0,684

Source: Results from SmartPLS analysis, 2023 data collected by the research team

Research results (Table 3) all show that the independent variable explains more than 50% of the predictive variability of the dependent variable. Specifically, the largest R-square adjusted is the variable YD with a value of 0.769; The smallest is the variable XH with R Square Adjusted reaching 0.562. Therefore, the authors found that the variables in the model have a good level of reflection.

➤ **Effect size f2 value (f squared)**

According to the results of Fig 5 f squared, the authors' analysis results are as follows:

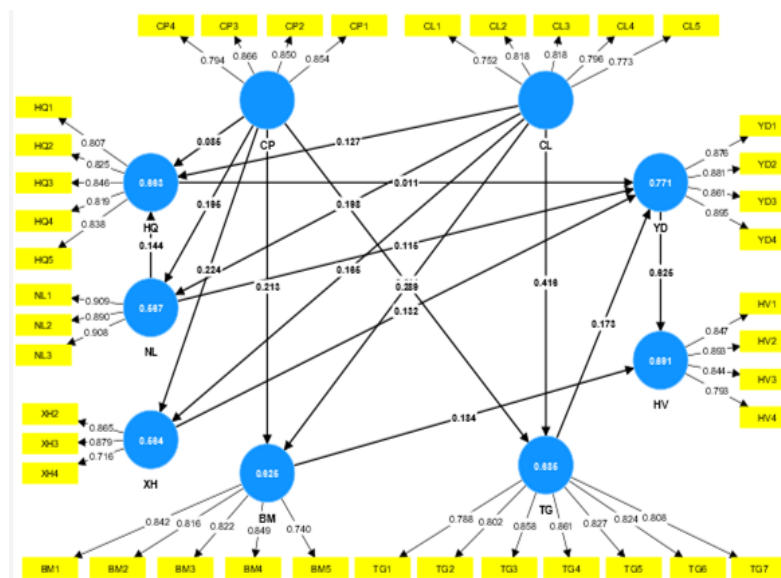

Fig 5. F square analysis results

Source: Results from SmartPLS analysis, 2023 data collected by the research team.

Firstly, Government Support and Quality of Digital Infrastructure both have a positive impact on Security, Performance Expectancy, Effort Expectancy, Payment Intermediaries, and Social Influence. Specifically, both CP and CL variables affect TG the strongest (0.244; 0.416); additionally, CL is considered to have a huge impact on TG because the f Square coefficient is in the range ≥ 0.35 (Cohen (1988)). Besides, CP and CL have the

lowest impact on HQ (0.085; 0.127), considering a small impact with the range of $0.02 \leq f^2 < 0.15$ (Cohen (1988)).

Secondly, Payment Intermediaries, Effort Expectancy, Social Influence, and Performance Expectancy have positive effects in descending order on Intent to Pay, respectively. Although the Performance Expectancy and Effort Expectancy factors have been widely accepted in many research papers such as Dao Thu Huong (2019); Dao My Hang et al. (2018); Wei et al. (2021), etc.; the authors' analysis shows that Payment Intermediaries (the highest f^2 (0.173)) and Social Influence (0.132) are the factors that have the highest impact on Intention to Use. Performance Expectancy according to the results is having little or no effect on Intention to Use (0.011). This might be true when Performance Expectancy no longer attracts the consumer's attention and influences their behavior.

Thirdly, the results also showed that Safety Security and Intention to Use have a medium and high impact on Usage Behavior, respectively. Moreover, Security is the only factor besides Intention to Use that directly affects Usage Behavior. It can be seen that in the current context, security is gradually getting more notice and may directly affect people's payment activities. Research by Luo et al. (2010) also shows that trustworthiness and safety have a significant influence on users' usage behavior.

Finally, Effort Expectancy is analyzed to have a small impact on Performance Expectancy, similar to the results of Venkatesh and Davis (2000).

➤ **Testing the intermediary relationship:**

Firstly, the results show that there is a difference in the level of influence between the separate indirect relationships of CP to HV. It is easy to see that $CP \rightarrow BM \rightarrow HV$ has the highest standardized regression coefficient with $\beta(CP) = 0.126$. Besides, the mediating effect level is respectively TG, XH, and NL, ($0.081 > 0.068 > 0.065$). The Government Support factor has included the legal element to present the Government's impact on Security and the intermediate impact on Usage Behavior. The results drawn from the group's analysis illustrate that CP affects HV through the mediated variable BM. This indicates a change in people's awareness compared to the conclusion of Nguyen Duy Khanh and Cao Hao Thi (2011): Legal factors have not been paid attention to and focused on in Vietnam. In fact, according to Kaspersky, in the first half of 2022, Vietnam detected and prevented 56,392 fake attacks targeting banks. Therefore, the legal factor affecting safety and security is currently a concern to people.

Secondly, the relationship of $CL \rightarrow BM \rightarrow HV$ (P value < 0.05 ; $T > 1.96$; $\beta(CL) = 0.147$) with the highest regression coefficient of all the mean effect relationships separate time between CL and HV; additionally, the results show the mediating effect of TG, NL, and XH decrease respectively.

The three Hypotheses $CP \rightarrow HQ \rightarrow YD \rightarrow HV$, $CP \rightarrow NL \rightarrow HQ \rightarrow YD \rightarrow HV$, and $CL \rightarrow NL \rightarrow HQ \rightarrow YD \rightarrow HV$ have all been rejected due to a P -value > 0.05 . This result can be explained by Fig 5, where the f -square value for Performance Expectancy is

considered to have the lowest impact and almost no effect on the Intention to Use E-payment (0.011). Additionally, this relationship involves multiple intermediate variables, which reduces the level of impact. Furthermore, Government Support has a weak effect on Performance Expectancy.

Comparing the influence between CL to HV and CP to HV depicts that the ranking of the relationship CP → BM → HV is in second place in terms of impact level, after CL → BM → HV, showing that to do well in security, the quality factor should be more concerned. Also, consider the relationship CL → TG → YD → HV, which is also higher than CP → TG → YD → HV. In addition, Performance Expectancy and Effort Expectancy no longer grab people's interest in electronic payments. This implies that amid the 4.0 revolution, the Government's primary effort to promote the digital economy is on businesses. The market economy (open economy) introduces many high technologies into Vietnam; as a result, people have high applicability and awareness; and focus on the quality of the electronic infrastructure and pay more attention to it. Due to market competition, technology growth changes strongly between domestic and foreign enterprises. Therefore, the products are gradually perfected and meet the maximum demand for use. However, CL → XH → YD → HV is lower than CP → XH → YD → HV. Hence, to promote the trend of not using cash, the Government should actively propagate and encourage the social community.

Table 4. Separate indirect impact results on Usage Behavior.

	Level of impact	T testing	P Value	Hypothesis testing
CP → BM → HV	0,126	5,691	0,000	Accepted
CP → TG → YD → HV	0,081	6,014	0,000	Accepted
CP → XH → YD → HV	0,068	5,354	0,000	Accepted
CP → NL → YD → HV	0,065	4,281	0,000	Accepted
CP → HQ → YD → HV	0,013	1,830	0,068	Rejected
CP → NL → HQ → YD → HV	0,007	1,859	0,063	Rejected
CL → BM → HV	0,147	7,083	0,000	Accepted
CL → TG → YD → HV	0,106	6,296	0,000	Accepted
CL → NL → YD → HV	0,066	5,413	0,000	Accepted
CL → XH → YD → HV	0,059	5,880	0,000	Accepted
CL → HQ → YD → HV	0,016	1,981	0,048	Accepted
CL → NL → HQ → YD → HV	0,007	1,896	0,058	Rejected

Source: Results from SmartPLS analysis, 2023 data collected by the research team

To test the relationship of aggregate indirect effects, the team continued to analyze and present in the table below:

Table 5. Summary table of indirect effects on Usage Behavior.

	Level of impact	T testing	P Value	Hypothesis testing
CL → HV	0,400	16,632	0,000	Accepted
CP → HV	0,360	14,599	0,000	Accepted

Source: Results from SmartPLS analysis, 2023 data collected by the research team

The analysis results show that the level of indirect effects from CL and CP to HV has $T > 1.96$; $P \text{ value} = 0.000 < 0.05$. Thus, there exists an indirect relationship between CL and CP to HV. The Total of the intermediate relationship will be equal to all the Specifics put together, so the Total of $CL > CP$ matches the result $(CL \rightarrow BM \rightarrow HV) > (CP \rightarrow BM \rightarrow HV)$.

Still, overall, Quality of Digital Infrastructure has the highest impact on Usage Behavior. From here, it can be seen that technology precedes management and follows; and technology development needs to be accompanied by governance to maintain stability and sustainable development.

5. Discussion and Conclusion

5.1. Policy implication

➤ For state management agencies

Firstly, it is necessary to advocate promoting the development of digital infrastructure to create a foundation for the growth of digital transformation in general and e-payment in particular. Sustainable development policies are needed to create a specific economic value with appropriate innovations for the future.

Secondly, the Government needs to orient, lead, and complete the legal framework related to payment risk management to ensure security, safety, and confidentiality in e-payment, as well as improve management and supervision activities for types, means, and electronic payment systems in Vietnam.

Thirdly, the Government needs to direct competent agencies to study and promulgate regulations on coordination mechanisms between credit institutions and payment intermediaries to create interconnection in payment, helping to save costs and increase convenience.

Finally, developing the electronic payment systems synchronously and continue directing local management agencies to promote communication activities to disseminate knowledge, raise awareness, and change behavior and consumer payment methods of both organizations and people; by that, improving access to and encouraging using electronic payment products and services in civil and commercial transactions.

➤ For businesses

Electronic payment services have been able to meet the existing desires of consumers; however, the development of electronic payment technology is slowing down. Therefore, to address this issue, businesses should actively innovate and develop their product ecosystem, expand new experiences, and strive for the best convenience.

Moreover, businesses need to focus more on digital infrastructure and technology to improve the electronic payment systems' efficiency, safety, and stability through regular updates and upgrades to ensure a smooth and trouble-free operation system.

In addition, businesses have to strengthen security by building and developing risk management programs for electronic payment systems or researching and applying new technologies for electronic payment systems, such as big data, blockchain, etc

5.2. Conclusion

This research is dedicated to revealing how digital transformation impacts the use of digital payment by Vietnamese people. Among the impacts of Digital Infrastructure Quality and Government Support to Usage Behavior through intermediate variables, the impact of Digital Infrastructure Quality on Usage Behavior is higher than that of Government Support.

Besides, the research also shows that Security and Payment Intermediaries are the two strongest intermediate variables that affect Usage Behavior. Expected Effectiveness has almost no direct impact on Usage Intention, and its role as an intermediate variable is also weak. Furthermore, there are differences in the Usage Behavior of Electronic Payment among age groups and residential areas of people.

Finally, the issues related to digital infrastructure and government support are multifaceted, and the current study did not delve deeply enough into their various factors, including the behavior of individual businesses. The most critical aspect, however, is the role of the government in ensuring the quality of digital infrastructure. This is an urgent matter since sustainable development of digital technology. Moreover, the study did not adequately address the social impact of digital infrastructure quality on usage behavior through intermediaries, despite clear evidence of its effects. Therefore, in future studies, the research team should narrow down the scope of businesses and conduct a more in-depth analysis of the social impact, government activities, and the catalyst effect of digital infrastructure in the digital transformation.

National Economics University, Hanoi, Vietnam

Abstract

The study aims to evaluate the impact of financial literacy (FL) on the ability of middle-aged people in Vietnam to access digital financial services (DFS), considering all three factors: financial knowledge, financial attitudes and financial behavior on accessibility to digital financial services (DFS) of middle-aged people in Vietnam. The research team utilised data collected through direct questionnaire surveys, and processed it through both quantitative and qualitative analysis, as well as in-depth interviews. The research results indicate that the factors of "financial knowledge," "financial attitude," and "financial behavior" are all positively correlated with the accessibility to DFS of middle-aged people in Vietnam. Based on these findings, the authors suggested some policy implications through programs and recommended policies with relevant agencies to enhance financial literacy and accessibility of middle-aged people to DFS in Vietnam.

Keywords: *financial literacy, digital financial services, digital economy, middle-aged, Vietnam.*

1. Introduction

In the digitalisation trend of industry 4.0, the financial services industry undergoes major changes, with technological driven innovations occurring in payments (instant payment, digital wallets) to credit (crowdfunding and online market lending), insurance (insuretech) and investment (robo-advice) to core banking (online digital banks), biometric identification or back-end support services (cloud-computing and big data) (OECD, 2020). These DFS benefit customers, financial institutions and the entire national economy, therefore, improving financial consumers' accessibility to DFS is essential in the current context.

However, DFS also poses significant challenges in choosing the suitable products and services and making accurate financial decisions for financial consumers. So as to do that, they need to be well aware of digital financial products and services in the market by

improving their FL. In Vietnam, the average FL level is very low, especially compared to other countries in the same region (Morgan and Trinh, 2019). According to Tran Thanh Thu et al. (2020), the level of interest in FL of Vietnamese people is lower than that of most Asian countries: the number of people with a high level of FL is only 24%, yet up to 93% of Vietnamese people do not intend to improve their FL.

As of 01/04/2019, the number of Vietnamese people in the middle-aged population group (45-65 years old) was 21.020.239, accounting for about 21,85% of the country's population and 32,13% of the labour force (15-65 years old). Middle-aged people contribute greatly to the economy because they tend to have higher incomes, spend more, generate tax revenue, contribute to social activities and create demand for products and services that stimulate employment growth. Lursadi and Mitchell (2011) have shown that middle-aged people have higher FL than younger or older people. However, middle-aged adults will often have difficulty learning and familiarizing themselves with technology, which, in turn, reduces their accessibility to DFS. As a result, improving FL and accessibility to DFS will help them realize the benefits of DFS, as well as protecting themselves against risks in the digital financial environment.

According to Morgan and Trinh (2020), FL has a positive correlation with Vietnamese people's accessibility to DFS. As a consequence, measuring the effects of FL on the accessibility to DFS of middle-aged people in Vietnam will contribute to taking appropriate measures to improve their level of FL and accessibility to DFS, improving the stability and development of the national economy.

In order to achieve the objectives of this study, in the next part, the authors will introduce literature review and overview of research. In Part 3, we will outline our research methodology, which is a combination of qualitative and quantitative research to analyze the effects of FL on accessibility to DFS. The research results (analysis of descriptive statistics and assessment of the impact of FL on middle-aged people's accessibility to DFS in Vietnam) will be presented in Part 4. Finally, Part 5 is the policy implications made based on the results of the research.

2. Literature review

2.1. Financial literacy

Previous studies have not yet provided a unified definition of FL (Gerrans and Heaney, 2016; Mabula and Ping, 2018). With a focus on financial knowledge, the OECD (2020) presents the most comprehensive definition of FL as “A combination of awareness, knowledge, skill, attitude and behaviour necessary to make sound financial decisions and ultimately achieve individual financial well-being”. With a focus on confidence in making responsible financial decisions, Warmath and Zimmerman (2019) have defined FL as the ability of a person to make effective financial decisions, where “competency” specifically refers to knowledge, skills, and self-efficacy. Kamiya (2017) associates the original definition of FL with “financial knowledge”, but the latest definitions now include or refer to the financial behavior of how consumers use and interact with the social and economic

environment. We found that the concept of FL includes several aspects: Financial knowledge (Kalekye and Memba, 2013; OECD, 2013; Lusardi and Mitchell, 2017; Kuntze et al., 2019; Ward and Lynch, 2019); Ability to communicate financial concepts (Remund, 2010); Ability to make sound financial decisions (OECD, 2020); Attitudes towards the use of financial products and services (OJK, 2021); Finance behavior (Vieira et al., 2018).

Therefore, we believe that FL is most related to concepts and ideas of financial knowledge, understanding concepts and applying them in the real world when making decisions about different options in financing activities such as saving and investing. We evaluate FL depending on three basic components: financial knowledge, financial behaviour, and financial attitudes.

(1) Financial knowledge

Financial knowledge is the most common element in many conceptual definitions of FL. Many previous studies have demonstrated the importance of financial knowledge directly affecting the level of access and effective use of main financial services. Specifically, people with higher financial knowledge are less likely to be taken advantage of or scammed (Andreou and Philip, 2018), less likely to take out loans beyond their ability to pay back (Lusardi and Tufano, 2015), well plan for retirement (Maarten van Rooij et al., 2012), participate more frequently in financial markets (Balloch et al., 2015) and have higher returns on savings accounts (Deuflhard et al., 2018).

(2) Financial attitude

The concept of financial attitude is defined as the mental state, viewpoint and financial judgement. Financial attitude affects how a person oversees financial management (Asih and Khafid, 2020); financial attitude shapes the way people save and spend money (Siswanti and Halida, 2020). Financial attitude plays a role in the individuals determining their attitudes and behaviours, both in terms of financial management, financial budgeting and decision making.

(3) Financial behaviour

There are many methods to define financial behaviour. Lusardi et al. (2010) assumes that financial behaviour is related to an individual's ability to project and manage personal finance in the direction of positive outcomes. Tezel (2015) describes financial behaviour as "the ability to capture the impact of financial decisions and correct decisions about cash management, precautions and opportunities for planning budget."

Many studies have proven that people with higher levels of FL are able to effectively participate in financial activities, such as deposits, mutual funds, and stocks (Yang et al., 2022). In addition, people with high FL established more mindful retirement planning (Clark et al., 2017) and sustainable investments (Aydin et al., 2019). On the other hand, low FL is related to limitations and restrictions in financial behaviour, such as less participation in financial markets (Bucher-Koenen et al., 2021), and making poor financial investment decisions (Lusardi and Mitchell, 2014).

2.2. Accessibility to digital financial services

According to the study of G20/OECD INFE in 2017, DFS can be defined as financial operations using digital technology, including electronic money, mobile financial services, online financial services, i-teller and branchless banking, whether through bank or non-bank institutions. DFS can encompass various monetary transactions, other financial products and services including payment, credit, saving, pensions and insurance and non-transactional services, such as viewing personal financial information through digital devices. From this perspective, in this study, the authors will focus on the accessibility of middle-aged Vietnamese to DFS in the following main areas: (1) Payment and money transfer, (2) Credit, (3) Savings, (4) Investment, (5) Insurance and (6) Budgeting and financial management.

Access to services means that people move forward, grasp and use the services that are necessary for their lives in the most effective and satisfying way. Hence, accessibility to DFS is the ability of people to be aware of and use DFS to satisfy their needs and benefit from it. In this study, we will approach DFS accessibility based on two dimensions: (1) being aware of the existence of DFS in the arrays mentioned above and (2) using those DFS. We chose to evaluate accessibility to DFS based on such two aspects because awareness of DFS is a prerequisite, a necessary condition for the use of that DFS. However, not everyone who is aware of the existence of DFS is willing to use that DFS, as financial conditions, individual demands, understanding of technology and digital finance, risk tolerance when starting to use a new service are different for each person.

2.3. Research hypotheses and model

a. Financial knowledge

Several studies have analyzed financial literacy for DFS adoption and use (Königsheim et al., 2017; Morgan and Trinh, 2019; Shen et al., 2018). Findings from both Kass-Hanna et al (2021) and Lyons and Kass-Hanna (2021) consistently indicate that financial literacy and digital literacy are key factors for building behavioral financial performance and long-term financial security. On the other hand, the lack of digital financial literacy is a potential threat to the financial economy, including individuals in the new age of digital banking.

⇒ H1: Financial literacy has an impact on middle-aged people's accessibility to digital financial services.

b. Financial attitude

The results of the study by Himawan and Wiyanto (2021) indicate that financial attitudes show a positive and significant impact on financial satisfaction and solutions in the use of non-cash payments. The results of another study, by Putri and Andarini (2022), show that a person's financial attitude can influence the use of Shopee pay in financial management. The results show that financial attitudes have a positive impact on Shopee pay service users. Foster and Johansyah (2022) suggest that financial attitudes have a significant positive effect on the use of cryptocurrencies. Thus, people with financial literacy and financial attitudes can encourage to use digital financial services such as digital wallets for payment.

⇒ H2: Financial attitudes have an impact on the accessibility to digital financial services of middle-aged people.

c. Financial behaviour

Several studies have attempted to discuss the relationship between DFS and financial behaviour. Garrett et al (2014) found that consumers using mobile payment devices are more likely to have high-cost debt, trouble with financial management, bad credit, card usage, and a lack of financial literacy. Yeo and Fisher (2017) investigated how online financial service users are affected by perceived behavioral control, subjective norm, and perceived usefulness.

⇒ H3: Financial behaviour affects middle-aged people's accessibility to digital financial services.

Synthesized from the above research hypotheses, we propose the following model:

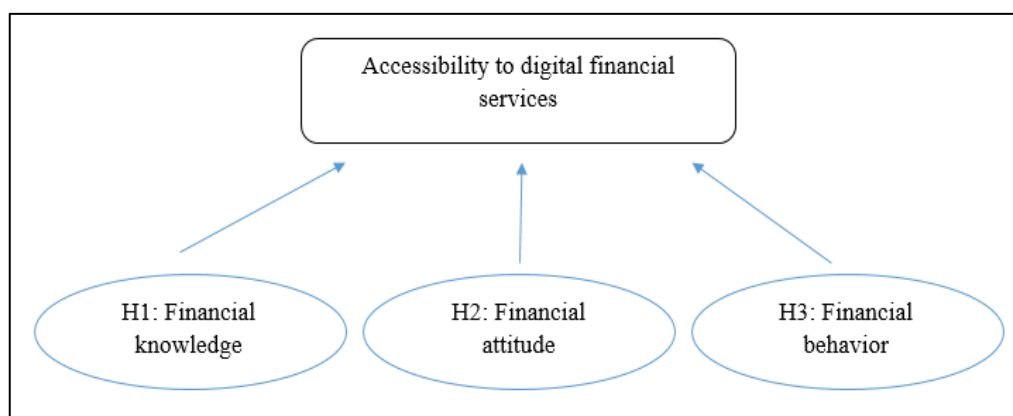

Figure 1. Research model

3. Method

3.1. Research methodology

In the scope of the research, the authors combined qualitative and quantitative research. Specifically:

Based on the synthesis and development of theories from previous studies, theories of financial literacy, accessibility to DFS, the authors have qualitatively analysed the factors affecting financial literacy and accessibility to digital financial services (DFS) among middle-aged people, as well as the impact of financial literacy on their access to DFS in Vietnam. At the same time, the study used quantitative methods and data modelling collected from individuals to obtain information on financial literacy, accessibility to DFS as well as other demographic information. The research developed a quantitative measurement scale for financial literacy and DFS access, where the set of indicators to measure financial literacy was constructed based on the OECD questionnaire (2015, 2016), research by Rooji et al. (2011), Ani Caroline Grigion Potrich et al.'s study (2016), Gian Paolo Stella et al.'s study (2019), and then adjusted to suit the middle-aged population in Vietnam. Specifically, the complete questionnaire to measure financial literacy included questions to measure Financial

knowledge (such as understanding of interest rates, inflation, time value of money, real value of money, stock market, definitions, and risk assessment, etc.); Financial attitudes (opinion on controlling spending/money management, willingness to invest/save or follow a spending plan, attitudes towards debt repayment, etc.); and Financial behaviors (cash management, budgeting/debt repayment/saving plans, etc.). The "Financial knowledge" scale consisted of 10 observation variables, the "Financial attitude" scale consisted of 8 observation variables, and the "Financial behavior" scale includes 8 observed variables. The survey tool was built based on observation variables measuring concepts in the model.

3.2. Research sample

The process of distributing survey questionnaires was collected from 20/12/2022 to 15/02/2023, mainly done online to save time and costs and increase access to middle-aged people and is also very consistent with the geographical distance between the researcher and the research object. After finishing, the author collected 1.117 answer sheets, went through the process of selection, cleaned the data by removing invalid answer sheets (only one column vote), and the total number of votes passed. The standard to include in the next analysis steps is 1.022 votes (accounting for 91,5%). The results of the descriptive statistics of the study sample obtained are as follows:

Regarding the gender of the study sample, there was not a big difference, and the proportion of women participating in the survey was higher than that of men, with 56% and 44%, respectively. This also shows that women have a certain level of interest in financial matters.

Regarding the living area, the authors found that in the survey, the number of respondents living in urban areas accounted for 77%, three times higher than in rural areas. This result can be explained by the fact that because the survey is mainly conducted using e-vouchers, the number of people in urban areas who have access to them will be higher than in rural areas. In addition, people living in urban areas will often have access to and be closer to financial issues than those in rural areas.

Regarding marital status, because the subjects of the research sample are middle-aged people, two common marital statuses are married and have children (69%) and married and have no children (14%). followed by middle-aged people who are unmarried at 12% and divorced at 5%.

In terms of education level, the majority of survey respondents have a university or college degree. From there, it is possible to ensure that the majority of people surveyed are mature and qualified enough to assess their accessibility to DFS objectively without being affected by transient subjective factors.

Regarding income, the group with income from 20 to 30 million VND/month has the highest proportion, at 35% of the total surveyed subjects. This is a stable income level compared to the conditions and living standards of many households and is common because their accumulated capacity and expertise in work increase over time, so this income level is reasonable.

4. Results and discussion

4.1. Descriptive statistic of accessibility to digital financial service

Regarding statistics on the awareness of digital financial products and services among middle-aged Vietnamese individuals: The proportion of middle-aged Vietnamese people acquainted with online payment services is overwhelmingly high (95%), primarily due to the impact of the Covid-19 pandemic and the government's promotion of online payments and other digital financial services in Vietnam. However, services such as credit, investment, insurance, and especially budget planning and management are considerably less prevalent, as these are not ubiquitous in everyday life.

Concerning the statistics on the utilisation of digital financial services among middle-aged Vietnamese individuals who are aware of them: The proportion of individuals utilizing online payment services is remarkably high (92%), indicating that this service is widely adopted in daily life. To satisfy their needs, users must inevitably execute payments for shopping or service usage. Conversely, services such as online savings, credit, insurance, investment, budget planning, and management are not obligatory necessities in life, so the proportion of middle-aged individuals who choose to use these services cannot be as dominant as online payments.

4.2. Impact of financial literacy on accessibility to digital financial services

After making EFA and CFA analysis to test the scale reliability and eliminate observable variables with unqualified loading factor, the authors obtained 6 factors observable variables with as:

Table 1. Summary of factors

No.	Factor	Observable variables	Type
1	Basic financial knowledge	FK1, FK2, FK3, FK4, FK5 (5 items)	Dependent
2	Advance financial knowledge	FK6, FK7, FK8, FK9 (4 items)	Dependent
3	Financial attitude	FA1, FA2, FA3, FA4, FA5, FA6, FA7, FA8 (8 items)	Dependent
4	Financial behavior	FB1, FB2, FB3, FB4, FB5, FB6, FB7, FB8 (8 items)	Dependent
5	Accessibility to DFS1	DFS1, DFS2, DFS3 (3 items)	Independent
6	Accessibility to DFS 2	DFS4, DFS5, DFS6 (3 items)	Independent
Number of dependent observable variables: 25			
Number of independent observable variables: 6			

Table 2. Model validity measures

Factor	Variable name	Composite Reliability (CR)	Average Variance Extracted (AVE)	Maximum Shared Variance (MSV)
Basic financial knowledge	FK_CB	0,929	0,622	0,319
Advance financial knowledge	FK_NC	0,908	0,554	0,319
Financial attitude	FA	0,839	0,515	0,105
Financial behavior	FB	0,805	0,512	0,100
Accessibility to DFS1	TC_1	0,767	0,529	0,418
Accessibility to DFS 2	TC_2	0,761	0,533	0,418

All factors have qualified composite reliability ($CR > 0,5$). The observed variables are unidirectional measuring a latent factor and uniquely represent a latent factor.

AVE are all higher than 0,5, showing that 6 factors meet the requirements for convergent validity. Moreover, MSV values are all smaller than the corresponding AVE values, which means 6 factors have no discriminant validity concern.

The authors continue to build structural equation modeling (SEM) as follows:

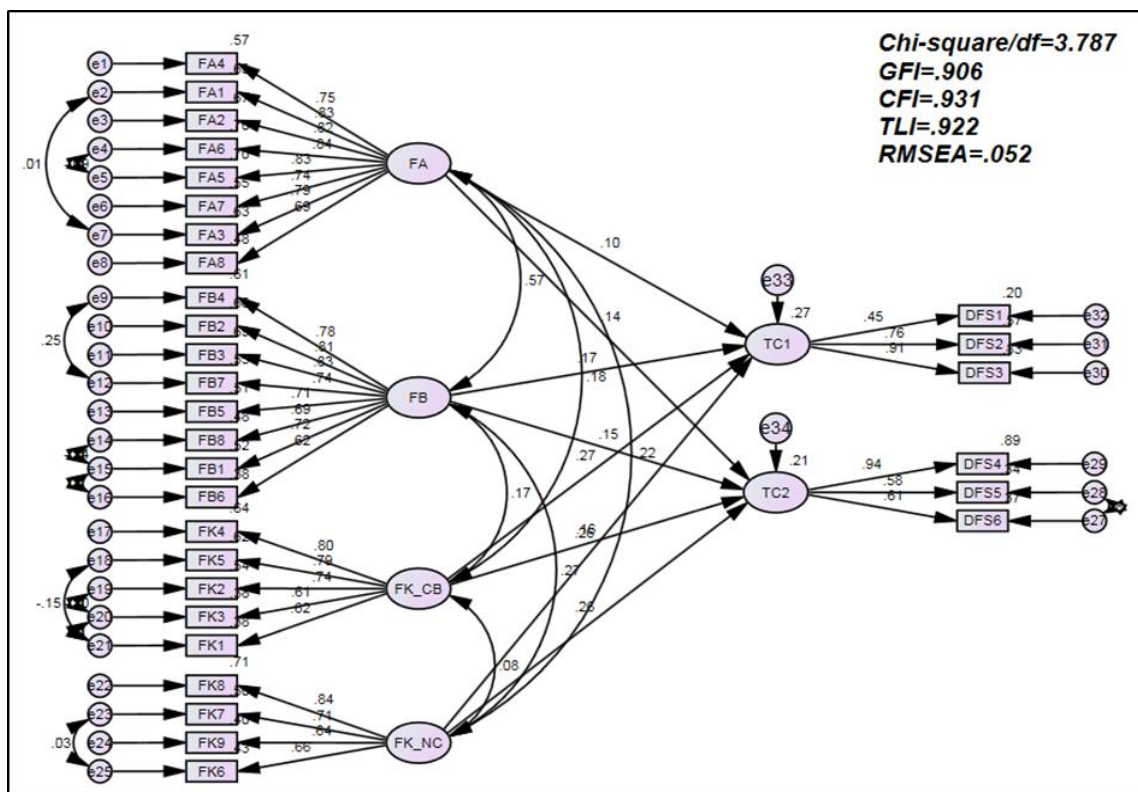

Figure 2. Structural Equation Modeling (SEM)

Table 3. SEM Standardised Regression Weights

Relationship between Variables			Standardised Regression Coefficient (SRC)	P-value
TC_1	←	FA	0,099	0,012
TC_1	←	FB	0,175	0,000
TC_1	←	FK_CB	0,266	0,000
TC_1	←	FK_NC	0,259	0,000
TC_2	←	FA	0,140	0,000
TC_2	←	FB	0,145	0,000
TC_2	←	FK_CB	0,157	0,000
TC_2	←	FK_NC	0,259	0,000

According to Table 3, all factors of the FL have P-value < 0.05, showing that with 95% confidence interval, these factors all have an impact on the likelihood of accessibility to both DFS groups (where TC_1 includes accessibility to services payment, savings and credit services; TC_2 group includes accessibility to insurance, investment, budgeting and financial management services).

Regarding the financial knowledge factor:

The SRC of FK_CB set in correlation with TC_1 is 0,266. This suggests that any increase in FL will lead to an increase in accessibility to payment, savings and credit services. Similarly, the SRC between FK_CB for TC_2 is 0,157. Consequently, we conclude that FK_CB has a positive relationship with the accessibility to insurance services, investment and financial management. FK_NC set in correlation with TC_1 and TC_2 both have a SRC of 0,259, showing that as financial knowledge is enhanced, it is positively correlated with DFS accessibility.

Positive relationship between FL and accessibility to DFS of middle-aged people can be explained by the following reason. As middle-aged people improve their financial knowledge, they will form the initiative to learn about financial services, thereby improving accessibility to DFS. Carrying the responsibilities of making decisions in household financial management, they need to be equipped with knowledge of financial products and services to ensure financial security in the digitalization trend and the rapidly developing context of DFS. Having good financial knowledge will increase the middle-aged group's level of readiness and confidence to adopt and use DFS.

Regarding the financial attitude factor:

The influence FA on TC_1 is 0,012, meaning that any increase in financial attitude will lead to an increase in access to payment, savings, and credit services. FA also has a positive relationship with TC_2 with a SRC of 0,140. It can be seen that if the financial attitude of middle-aged individuals becomes better, they will develop self-awareness about financial services, thereby enhancing their ability to access DFS.

When someone has a good financial attitude, it leads to appropriate and correct financial behaviour, thereby expanding financial opportunities and closer access to DFS. Financial attitude affects how someone adjusts their financial behaviour, thereby creating an impact on DFS access. This is especially true for middle-aged individuals, most of whom have equipped themselves with certain financial knowledge and formed an attitude towards finance, gradually they actively participate in financial services and enhance their ability to access DFS.

Regarding the financial behaviour factor:

FB has a SRC of 0,175 in the correlation with TC_1, indicating a positive correlation, specifically when FB increases by 1 unit, it will increase TC_1 by 0,175 units. Therefore, financial behaviour is a factor that promotes the ability to access payment, savings, and credit services. In the relationship with TC_2, the SRC of FB is 0,145, showing that financial behaviour has a positive impact on the ability to access insurance, investment, budgeting, and financial management services: when FB increases by 1 unit, TC_2 increases by 0,145 units.

Along with the growth of the financial system, the development of technology, financial behaviour is increasingly perfected, and the sensitivity of middle-aged individuals to changes in the economy also increases, thereby reacting faster to the changes in digital financial services. Therefore, as the financial behaviour of middle-aged individuals improves, they have more opportunities to access a diverse range of digital financial services.

5. Discussion and Conclusion

At present, digital financial literacy remains relatively novel for the Vietnamese population, especially among middle-aged individuals. The challenges of acquiring new knowledge are compounded by their limited learning capacity compared to younger generations. Consequently, establishing guidance to enhance digital financial literacy faces significant obstacles. With a developing economy and burgeoning technology, numerous digital financial services have emerged in the market. Insufficient digital financial literacy adversely affects the accessibility of these services for middle-aged Vietnamese individuals in the current context. Based on this reality, the authors propose solutions to improve digital financial literacy in tandem with the direct dissemination of digital financial services to consumers, providing them with hands-on experience. Practical implementation proves considerably more beneficial than solely relying on theoretical instruction or hearing promotional messages.

Programs aimed at enhancing digital financial literacy, along with practical experiences, should be flexible and monitored for timely adjustments to suit the learning capacity of different target groups. Information from these programs should be derived from reputable sources, easily recognizable to facilitate comprehension and accessibility. Simplifying communication and standardising theoretical frameworks will enable middle-aged individuals to absorb this knowledge more effectively.

The government and local authorities should facilitate the widespread implementation of digital financial services within their jurisdictions. Additionally, policies

should encourage middle-aged individuals with limited education to proactively consolidate and improve their digital financial literacy. Moreover, support policies should enable middle-aged individuals to readily possess electronic devices and stimulate consumption of digital financial products and services, indirectly elevating living standards and fostering local economic development.

Abstract

The present study focuses on examining the interplay and correlation between the digital transformation process as assessed by the digital banking service quality components (Ease of use, Effectiveness, Interoperability, Privacy/ Security, Empathy, Responsiveness, Reliability, Service portfolios, Service charge) and customer satisfaction for digital banking services at commercial banks in Vietnam. The predictors (independent variables) for this study are the aforementioned service quality aspects and moderator is Service charge. The outcome variable (dependent variable) is customer satisfaction. The authors combined qualitative and quantitative research techniques to develop observed variables and assess the model's fit. This study can help banking leaders evaluate and improve the quality of digital banking services in the context of financial liberalization and globalization.

Keywords: *Banking service quality, Customer satisfaction, Digital Banking, Digital Transformation*

1. Introduction

In Vietnam, the government's program "National transition to 2025, orientation to 2030" has clearly stated that finance and banking is one of the fields with great social impact; and digitization should be prioritized. The requirement for banks is to improve the quality of digital banking services to meet the needs and improve customer satisfaction. The benefits of e-banking are great for customers, banks and the economy, thanks to its convenience, convenience, speed, accuracy and security (Do Van Huu, 2005). Service quality assessment

is an important leadership task needed to achieve organizational success (Glaveli et al., 2006). Cronin and Taylor (1992) described five dimensions (tangibility, reliability, responsiveness, assurance, and empathy) that constitute customer expectations of service. When information technology is applied to banks, the concept of electronic banking (e-banking) was born to create a new service platform to serve the requirements of a set of customers who have already participated and transferred change in the digital environment (Nguyen Thuy Trang, 2018). Therefore, a big requirement for Vietnamese banks today is to actively develop and improve the quality of e-banking services in order to best meet customer needs.

When deploying e-banking services at banks in Vietnam, the nature of the service environment has changed significantly, that is, the transition from the traditional environment to the online environment with a technology platform. Therefore, the traditional banking service quality assessment model will no longer be suitable with traditional scales, combining with the deployed e-banking service, it will require new scales to match with the new service deployed on the bank's e-banking platforms. Service Quality improvement is a key issue determining the very survival of the bank itself. The gap-model of the SERVQUAL instrument (Parasuraman et al., 1991) and BSQ models, that compares the perception of performance (P) to expectation (E), has been widely used in past studies in a variety of industries. This study will attempt to utilize the SERVQUAL measurement of Parasuraman, Zeithaml, and Berry (1991) in determining the existence of 'service-gaps' in commercial banks of Vietnam.

2. Literature review and Theoretical framework

2.1. Literature review

Regarding foreign studies, there are some typical studies that focus on customer experience and satisfaction when researching into the field of digital transformation. Research by Nuri and Andi (2018) examines the influence of service quality from four aspects: operational aspect, physical aspect, new technology and human aspect on customer experience. The study concludes that new operational and technological aspects have a significant contribution to customer experience, thereby creating customer satisfaction and customer loyalty in the context of Islamic banking. Firas et al (2021) researched and found out how digital transformation positively affects customer experience in the Palestinian banking sector because it makes the banking experience easier, faster and more flexible, helping to improve customer satisfaction and satisfaction. In Vietnam, the authors Trang Doan Do et al (2022) have concluded that quantitative transformation has a positive impact on the performance of Vietnamese commercial banks.

After reviewing relevant studies, the research team has discovered gaps and factors that are not suitable with the actual situation at banks as well as the consumer tastes of customers in Vietnam. Vietnam. Firstly, digital transformation has become a popular trend in economic sectors all over the world and has been deeply explored by many researchers. However, in the banking sector in Vietnam, there have not been many studies related to this

topic. Secondly, in terms of time, after the Covid-19 pandemic, customers' behavior and habits have changed a lot, especially in the banking sector. However, there are too few studies related to the influence of digital transformation on customer satisfaction with digital banking services in Vietnam, especially in the context of the ongoing Covid-19 pandemic. Third, in the field of Digital Banking, service quality is an important factor to help the Bank enhance its reliability and create trust for customers. However, the number of studies are too modest related to the quality of digital banking services, especially in Vietnam. In addition, the research team found that there are no previous documents or studies that have investigated or described the impact of digital banking services in commercial banks in Vietnam on customer satisfaction. We therefore believe that the results of this study will be unique and will complement this issue.

2.2. Theoretical framework

Digital banking and digital banking services

Digital banking includes the transition from traditional banking to technology-based banking, in which banking services are managed for customers through a series of open and customized channels such as machines and computers. automatic withdrawal (ATM) and mobile platform, online/Internet. These channels present a popular opportunity for banks to offer services to their customers such as mobile and online banking, text messaging, electronic reporting and bill payment. With digital banking, customers have the opportunity to fulfill their banking needs without going to a physical branch (Kimenyi et al., 2009).

Digital banking services as defined by Chikoko and Munongo (2015) is the use of the internet, mobile phones and any other electronic means as a distribution channel for banking services, including all services. traditional banking services such as balance inquiry, statement printing, transfers, transfer of funds to other accounts, bill payment, and new banking services such as presenting and paying electronic bills without necessarily visiting bank.

Quality of digital banking services (e-SERVQUAL)

For the digital banking, assessing customer service quality perceptions is becoming increasingly important and strategic for banks (Huei et al., 2018). Since Parasuraman et al. (1988) introduced a 22-item scale, called SERVQUAL, to measure service quality, this model has been widely applied across industries. The focus of SERVQUAL lies in the five dimensions of service quality made possible by an indirect (or objective) comparison between pre-purchase expectations and post-purchase perceptions of a company's performance. Previously, Yang & Jun (2002) also confirmed that there are 6 factors, namely: reliability, accessibility, ease of use, personalization, security and reputation that affect service quality. However, approaching from the perspective of customer satisfaction on the internet, Zeithaml et al (2000, 2002) have proposed an e-SERVQUAL model that includes 7 influencing factors: efficiency, synchronization, and reliability, personal data protection, response, reimbursement and contact. On that basis, Gerrard & Cunningham (2015) have studied more specifically with satisfaction with the quality of banking services on the internet including: presence, ease of use, reliability, responsiveness, safety, service situation,

staff quality. This result reinforces the study of Chu et al (2012) on the relationship between internet service quality, relationship quality and customer loyalty, which has shown relatively specific factors affecting affect internet banking.

2.3. Research model and hypotheses

Based on a review of the literature on service quality assessment guided by the adopted ES-QUAL and CLDVNHS models, the authors come to the conclusion that the combination of these two models will complement each other to provide a comprehensive understanding of the various aspects affecting customer satisfaction. Therefore, the research team proposes the following research model:

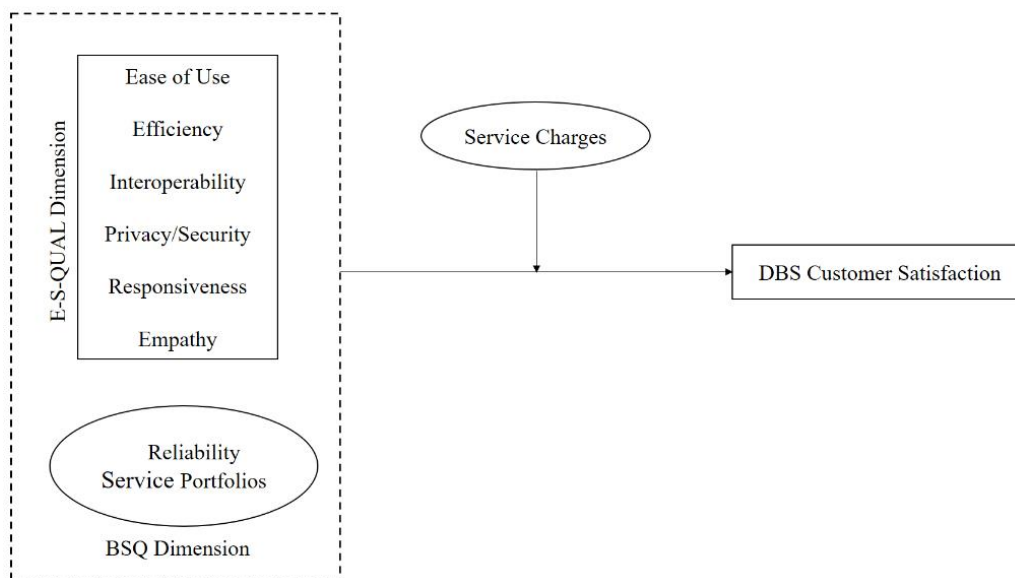

Figure 1. The impact of Digital Transformation on Customer Satisfaction to Digital Banking Service of Commercial Banks

Research hypothesis

➤ *Ease of use*

The user-friendliness of digital programs is described by their ease of use (Parasuraman et al., 2005). The simplicity of use has a major impact on utilization and customer satisfaction, according to Ketema and Selassie (2020), who evaluated banking apps during the COVID-19 pandemic. Similar to this, earlier research (Simon and Senaji, 2016; Zavareh et al., 2012) came to the conclusion that the usability of e-services has an impact on customer satisfaction. Therefore, this study hypothesized that:

H1: Ease of use of DB services is positively related with customer satisfaction

➤ *Efficiency*

Efficiency affects how quickly a platform can offer customers flexible financial assistance and how easily a digital platform can handle customer support queries (Ariff et al., 2013). According to Ankrah (2012), enhanced operational efficiency in the banking sector of Ghana has the potential to yield strategic advantages including increased customer satisfaction.

According to this, John and Rotimi (2014) contend that efficiency is still crucial for promoting electronic consumer satisfaction in Nigeria's banking sector. Also, recent research demonstrates that efficiency has a substantial impact on the pleasure of online customers (Amin, 2016; Raza et al., 2020). Given these perspectives, this study hypothesized that:

H2. The efficiency of the DB is positively related with customer satisfaction

➤ *Interoperability*

The capacity of an DB technology to connect to and communicate with other electronic banking systems is known as interoperability (Gupta et al., 2017). The national mobile money interoperability infrastructure in Ghana, for instance, has been integrated by banks to let users move money between two bank accounts or between many entities (GSMA, 2020). Bank customers are required to use the available platforms to carry out a range of financial activities because of the limitations placed on people during the COVID-19 epidemic (Kelecic, 2020). Moreover, Bourreau and Valetti (2015) contend that interoperability drastically lowers consumer conversions and related expenses because e-customers no longer need to switch between several digital platforms in order to carry out a similar task. According to this research (Bourreau and Valetti, 2015; Kelecic, 2020), there is a strong and positive correlation between Interoperability and consumer happiness. Therefore, we hypothesize that:

H3. DB applications interoperability is positively related with customer satisfaction

➤ *Privacy and security*

The security and privacy dimension evaluate how well a bank's digital platform safeguards the private and financial data of its customers (Parasuraman et al., 2005). Security is a significant issue in how customers perceive the quality of the services provided at COVID-19 in Ethiopia, according to Ketema and Selassie (2020). This claim is accurate because there are several security concerns caused by the limits placed on people that force them to rely solely on their DB applications for their financial transactions. According to research by Ketema and Selassie (2020), the level of security offered by mobile banking platforms has a big impact on how satisfied and trusted customers are. Customer happiness and the privacy/security of DB services are positively and significantly correlated, according to research by Ketema and Selassie (2020). Finally, we hypothesize that:

H4. The privacy/security of the DB service application is positively related with customer satisfaction

➤ *Empathy*

Empathy involves providing care and attention to individual clients (Parasuraman et al., 1988). Parasuraman et al. (1994) pointed out that quantitative research has acknowledged archetypal aspects of service quality including philanthropic safety, reliability, as well as empathy-level exposure. Potluri et al. (2016) describes empathy as the ability to take care of customers and show devotion to them independently, especially while providing services. Similarly, studies by Siddiqi (2011) in Bangladesh confirmed that empathy highly predicts customer satisfaction. Therefore, the next hypothesis stated is:

H5. The empathy of the DB service application is positively related with customer satisfaction

➤ *Responsiveness*

The willingness to assist clients and render prompt service is referred to as responsiveness (Akinyemi et al., 2010; Parasuraman et al., 2005). The capacity to promptly and professionally recover after a bank's digital service failure or outage can frequently produce a very positive sense of quality (Zavareh et al., 2012). Narteh (2018) draws the conclusion that a bank's capacity to provide high-quality service has an impact on customers' happiness in Ghana. Past research has demonstrated that customer happiness is impacted by the DB's response (Narteh, 2018; Al-Ghraibah, 2020). Therefore, in this study, we hypothesize that:

H6: DB service responsiveness is positively related with customer satisfaction

➤ *Reliability*

The DB platform's reliability is described as its capacity to carry out its functions in accordance with clearly defined mission characteristics without making mistakes (Bahia and Nantel, 2000; Parasuraman et al., 2005). According to Parasuraman et al. (1988), one of the most crucial aspects of service quality is reliability since customers want to know that the registered services can fully provide the service they have been promised adequate and precise (Parasuraman et al., 2005). Given that results in the provision of high-caliber services Customers' pleasure and loyalty are positively impacted by DB reliability, according to research by Raza et al. (2020) and Narteh (2018). Therefore, in this study, we hypothesize that:

H7. DB reliability is positively related with customer satisfaction

➤ *Service portfolios*

According to Bahia and Nantel (2000), the service portfolio refers to a collection of cutting-edge goods and services that adhere to its mission statement. Banks have shifted the majority of their traditional services to their digital platforms as a result of constraints put in place due to the COVID-19 epidemic. Customers, on the other side, are eager to anticipate bundled services on a consolidated platform from which they can (Mersha and Worku, 2020). Ghana's banking sector is competitive mostly as a result of the constant introduction of novel goods and services (Addai et al., 2019). It is clear that the service category significantly predicts customer satisfaction (Petridou et al., 2007; Narteh, 2018). Therefore, this study hypothesized that:

H8. The service portfolio of the DB applications is positively related with customer satisfaction

➤ *Moderator: Services charge*

Service fees are expenses related to using or gaining access to the DB (Bahia and Nantel, 2000). Senyo and Osabutey (2020) found that Ghanaian users of mobile banking were concerned about the cost of each transaction and came to the conclusion that lowering service prices would greatly increase customer satisfaction. There is evidence that the price-

quality relationship has not been thoroughly investigated (Kim et al., 2006, Toncar et al., 2010). In a recent study, Toncar et al. (2010) discovered that customers' evaluations of the quality of the service are influenced by the extent to which their fees expectations are realized. This leads us to conclude that clients' expectations for the amount they will pay will affect how good of a service they will receive. The charge a consumer anticipates paying for a specific service is known as the expected charge (Toncar et al., 2010). Fees fairness affects the customer's faith in and happiness with the service provider, according to Kim et al. (2006). As a result, in this study, we choose "service charge" as a moderate variable and propose the following hypothesis:

H9. DB service charge moderates the relationship between service quality of the bank and customer satisfaction

3. Method

Data collection: This study used survey questionnaires, both direct and indirect questionnaires with statistics analysis. The research team has collected 505 users of digital banking services in Vietnam who were surveyed using online forms and questionnaires created on a Google Docs Forms page.

Participants: The survey results showed that there was no significant gender difference between the survey participants: 220 of the survey participants were male (43.56%) and the remaining 285 survey (56.44%) participants were female. Statistical results on age show that the majority of survey respondents are between the ages of 18 and 39, accounting for 71.28%. Statistical results of survey respondents by education level show that the majority of respondents to the survey have an education level from high school or higher, of which the number of people with a university degree accounts for the highest percentage (64.95%). Meanwhile, the number of people with education level from upper secondary or lower and intermediate and advanced is very low, including only 24 people (4.75%). Finally, in terms of average income, 200 survey respondents had an income from 10 to 20 million dong (39.60%). The number of people with incomes from under 10 million dong and from 20 to 30 million dong were quite similar, were 130 (25.74%) and 119 (23.56%) respectively.

Data analysis: After collecting data, the authors synthesized, screened, coded and processed the data through SPSS software version 22.0 and AMOS. First, evaluating Cronbach's Alpha coefficient to assess the reliability of the scales, and at the same time evaluating the correlation coefficient of total variables to eliminate unsatisfactory observed variables. Exploratory factor analysis EFA and confirmatory factor analysis CFA were used to conclude the quality of the scale and the suitability of the proposed research model, preparing for the testing of the research hypothesis. Lastly, using linear structural model SEM with covariance-based approach (CB-SEM) to test the research model and research hypotheses.

4. Results

Reliability assessment

The results indicated that the Cronbach's alpha coefficient of the measurement scales were all above 0,7 criteria, specifically, $\alpha_{EOUS} = 0,820$, $\alpha_{EFF} = 0,743$, $\alpha_{INTE} = 0,804$, $\alpha_{SECU} = 0,712$, $\alpha_{EMP} = 0,912$, $\alpha_{RES} = 0,879$, $\alpha_{REL} = 0,755$, $\alpha_{SEPO} = 0,808$, $\alpha_{SEC} = 0,762$, $\alpha_{SAT} = 0,771$. Moreover, all observed variables in each measurement scale had inter-item correlation of the total score above 0,3, except for the observed variable of SAT1, which only reached a correlation coefficient of 0,228. Additionally, the inter-item correlation of the total score for SAT was only 0,322, which decreased the Cronbach's alpha value of the measurement scale. Therefore, the research team decided to remove the SEC1 and SAT1 variables from the model to improve the reliability of the measurement scales. As a result, it can be concluded that all of the measurement scales achieved consistent reliability, and 36 out of 38 observed variables were retained for further analysis in subsequent steps.

After using Cronbach's alpha coefficient to eliminate invalid observed variables, the research team conducted exploratory factor analysis (EFA) with Promax oblique rotation and Principal Axis Factoring extraction on all 36 observations of the factors. The Kaiser-Meyer-Olkin measure was 0.874, indicating that the data was suitable for factor analysis (Hair et al., 2009). The significance level of the Bartlett's test was Sig = 0.000, which confirms that the variables are intercorrelated in the population. All 36 variables were extracted into 10 factors with Eigenvalues greater than 1, with a total variance explained of 58,010%, indicating that the 10 factors account for 58,632% of the data variability. Thus, it can be concluded that the model is appropriate and the 10 factors can explain the data.

Confirmatory factor analysis (CFA)

The resulting fit indices for the model are were follows: $CMIN/df = 1,480 \leq 2$, $GFI = 0,916 \geq 0,8$, $CFI = 0,967$, $TLI = 0,962 \geq 0,9$, and $RMSEA = 0,031 \leq 0,08$. Based on these analyses, it can be concluded that all fit indices meet the required standards, affirming the appropriateness of the research model (Hair et al., 2010)

The results of Table 2 show that the CR of all constructs exceeds the recommended value of 0,6. Additionally, while most constructs have AVE values above the threshold of 0,5, the AVE of SEC, SECU, and EFF only reached 0,456, 0,466, and 0,491, respectively (close to but below 0,5). However, Fornell and Larcker (1981) suggested that when AVE values are below 0,5, but CR values are above 0,6 (the CR values of SEC, SECU, and EFF are 0,805, 0,715, and 0,439, respectively), the convergence value is still acceptable. Therefore, all measurement scales ensure reliability and discriminant validity (Hair et al., 2020).

Structural Equation Modeling (SEM) Analysis

The results of the goodness-of-fit test for the linear Structural Equation Modeling (SEM) show that the indices are as follows: $CMIN/df = 1,526 \leq 2$, $GFI = 0,925 \geq 0,9$, $CFI = 0,970 \geq 0,9$, $TLI = 0,965 \geq 0,9$, and $RMSEA = 0,032 \leq 0,08$. Therefore, it can be concluded that the research model fits relatively well with the market data (Hair et al., 2010)

Figure 2. Normalized structural model

Table 1. Hypothesis test

	Path	β	S.E.	C.R.	P-value	Decision
H1	EOUS \rightarrow SAT	0,277	0,063	4,387	***	Supported
H2	EFF \rightarrow SAT	0,318	0,095	3,353	***	Supported
H3	INTE \rightarrow SAT	0,101	0,051	1,966	0,049	Supported
H4	SECU \rightarrow SAT	0,166	0,051	3,257	0,001	Supported
H5	EMP \rightarrow SAT	0,122	0,036	3,417	***	Supported
H6	RES \rightarrow SAT	0,130	0,060	2,181	0,029	Supported
H7	REL \rightarrow SAT	0,124	0,057	2,199	0,028	Supported
H8	SEPO \rightarrow SAT	0,135	0,055	2,480	0,013	Supported

The findings indicate that all hypotheses H1, H2, H3, H4, H5, H6, H7, H8 are supported at a statistically significant level of 5%. Specifically, Ease of use and Effectiveness have positive and the most significant influence on customer satisfaction (H1: $\beta = 0,277$, p-value = $0,000 < 0,05$), (H2: $\beta = 0,317$, p-value = $0,000 < 0,05$). Interoperability, Security, Empathy, Responsiveness, Reliability and Service Portfolio all have strong and positive impact on customer satisfaction (H3: $\beta = 0,101$, p-value = $0,0049 < 0,05$), (H4: $\beta = 0,166$, p-value = $0,001 < 0,05$), (H5: $\beta = 0,122$, p-value = $0,000 < 0,05$), (H6: $\beta = 0,122$, p-value = $0,029 < 0,05$), (H7: $\beta = 0,124$, p-value = $0,028 < 0,05$), (H8: $\beta = 0,124$, p-value = $0,028 < 0,05$)

Table 2. Moderating hypothesis test

	Path	β	S.E.	t	P-value	Decision
H9a	EOUS * SEC \rightarrow SAT	0,2553	0,0711	3,5901	0,0004	Supported

H9c	INTE * SEC \rightarrow SAT	0,2353	0,0470	5,0079	0,0000	Supported
H9d	SECU * SEC \rightarrow SAT	0,2253	0,0613	3,6762	0,0003	Supported
H9e	RES * SEC \rightarrow SAT	0,3475	0,0555	6,2585	0,0000	Supported
H9f	EMP * SEC \rightarrow SAT	0,1352	0,0528	2,5593	0,0108	Supported
H9g	REL * SEC \rightarrow SAT	0,2269	0,0717	3,1673	0,0016	Supported
H9h	SEPO * SEC \rightarrow SAT	0,3241	0,0940	3,4488	0,0006	Supported

Regarding the moderating hypothesis, the analysis results show that all the moderating hypothesis H9 are accepted at a statistically significant level of 5%.

5. Discussion and Conclusion

5.1. Discussion

The independent factors "easy of use, efficiency, interoperability, security/privacy, insight comprehension, response, dependability and service category" all have a positive or negative impact on the dependent variable "satisfaction," according to the hypotheses H1, H2, H3, H4, H5, H6, H7, and H8. This finding is consistent with earlier studies by Egala (2019), Al-Ghraibah (2020), Ankrah (2012), and Ketema and Selassie (2020). In online banking, each single feature of effectiveness, system availability, fulfillment, privacy, contact, feedback, and individual. Although Ul Haq and Awan (2020) found that consumer happiness is connected with the privacy and security of digital applications, this association depends on the privacy and security of the platform. The study's findings are particularly significant because Ketema and Selassie (2020) discovered a link between customer happiness and how simple SQDB applications are to use. Similar findings are made for the variable "understanding" in Van Dinh and Lee Pickler's (2012) investigation of the connection between service quality and customer satisfaction in the retail banking industry. When employing multiple regression equations, knowledge and dependability have a considerably larger rate of positive influence than the other variables, with significant contributions of 0.26 and 0.28. This outcome is in line with the findings of Murali et al.

(2016) and Al-Ghraibah (2020), who discovered a connection between high-quality digital services and customer satisfaction and intention to stick around. In contrast to Agala's study from 2021, his other hypotheses, such as interoperability, responsiveness, and service category, had no effect on customer satisfaction. Yet, this outcome is consistent with the findings of the research team when the independent variable "Services charge" is allowed to operate as a moderator in the association between consumer happiness and the quality of digital banking services. The results demonstrate that the connection between independent factors and dependent variables is positively impacted by service fees. Service charge is an important factor for meeting customer demand for digital banking services of commercial banks in Vietnam, specifically, reasonable service charges can enhance customer satisfaction with service quality and strengthen the link between customers and the bank.

5.2. Summary and recommendations

In this study, we investigate how different facets of digital banking services offered by Vietnamese commercial banks impacted Vietnam as a whole and the banking sector in particular throughout the period of digital transformation. The Covid-19 pandemic, when digital transformation is viewed as a strategic and unavoidable step of the economy, and the rising popularity of "mobile banks" among Vietnamese banking service users served as the impetus for this study. The model put forth by the research team is entirely appropriate and has surprisingly precise predictions, according to the findings of the confirmatory factor analysis CFA in the preceding chapter. Theoretically, the research has contributed to building a model to evaluate the effect of digital transformation on customer satisfaction through measuring the quality of digital banking services in Vietnam. Indeed, the 9 aspects that the research team found have a positive effect on customer satisfaction in descending order as follows: Efficiency, Ease of use, Security and privacy, Service Category, Responsiveness, Reliability, Understanding, Interoperability. This is the basis for researchers to develop topics related to digital transformation in the future.

The research results of the project help commercial banks to save costs in researching and understanding the market. In the context of large competitive credit institutions in many fields, customer retention is therefore essential. Finding out about their experiences is a crucial step in being able to guarantee the accuracy of the information provided to customers. Managers can now concentrate their resources on creating a digital bank in the most efficient manner thanks to the research's identification of crucial aspects of the process of digital transformation that have an impact on customer satisfaction. Commercial banks can make strategic adjustments for business operations based on the topic and the precise information provided by the author group, which will help them better understand the needs of customers.

5.3. Conclusion

The aim of this research was to examine how quality DBS (digital banking services) affects customer satisfaction and retention intentions, using the E-S-QUAL and BSQ models. We collected 505 responses and at the end of the result analysis, it emerged that DBS satisfaction directly impacts on customers' retention intentions. Specifically, the study

is based on eight quality dimensions namely ease of use, efficiency, interoperability, privacy/security, responsibility, reliability, empathy and portfolio. Moreover, service charge has a role as a regulator variable. It emerged that ease of use, efficiency, interoperability, privacy/security, responsibility, reliability, empathy and portfolio of DBS impacts on customers' retention decision when satisfied. Although some portions of the study findings were inconsistent with prior studies, it offers an opportunity for further assessment in contribution to a broader knowledge of quality banking services.

Abstract

This study uses an empirical method to determine the influence of different display placements of online advertising and different numbers of identical online ads on the brand perception of viewers. Based on the theory of brand recognition within the theory of brand awareness, the article points out the influence of two factors, which are: different placements of online advertising and different numbers of online identical ads on the brand recognition ability of viewers who are students in Hanoi. Experimental results show that both of these two factors will have different levels of influence on the viewer's ability to recognize the brand, namely the ability to recognize the brand name and the ability to recognize the brand's advertising image.

Keywords: *Advertising, Online advertising, Brand Awareness, Banner, Brand Recognition, Advertising Frequency, Pop-up, Ad Placement, Skyscraper, Website.*

1. Introduction

Online advertising involves delivering advertisements to Internet users via Web sites, e-mail, ad-supported software, and Internet-enabled smart phones. The purpose of the internet ads is to inform users of the wide range of products and services on offer. Examples of online advertising include contextual ads on search engine results pages, banner ads, rich media ads, social network advertising, interstitial ads, online classified advertising, advertising networks, and email marketing, including email spam. Online advertisements

may be classified into floating ads, expanding ads, pop-ups, wallpaper ads, trick banners, and pop-unders, among others (Backshi and Gupta, 2013). However, for the purposes of this research, banner ads, skyscraper ads, and pop-up ads are examined.

Mass communication that is based on traditional advertising is known as online advertising. Online advertising is the dissemination of advertisements to Internet users via websites, email, ad-supported programs, and Internet-connected cell phones. Contextual advertising on search engine results pages, banner ads, rich media ads, social media ads, interstitials, commercials, online classified ads, advertising networks, and email marketing, including email spam, are a few examples of online advertising.

One of the forms of online advertising is advertising on websites as well as on other platforms like social networks and blogs (Yang et al., 2016). Consumers' knowledge of brands increases thanks to the use of online advertising, especially advertising on websites (Alamsya et al., 2021).

Previous research has discovered and investigated elements like the degree of the promoted product's engagement (Yoon 2001), the brand's familiarity (Dahlen 2001), and the viewer's Internet experience. (Bruner 2000), all of which have a significant impact on how sympathetic consumers are to the promoted product or brand and how likely they are to make a purchase (Gallagher 2001). Other research has concentrated on looking at elements relating to the design of the advertisement itself, such as the placement of the advertisement (Benway & Lane 1998) and the frequency of the display of advertisement pictures. 2015 (Schmidt & Eisend).

However, studies examining the effectiveness of advertising, such as the level of recall and recognition of advertising images, are few, leading to a lack of research on the possibility of advertising. remember in each different online advertising placement or remember the viewer's level of memory with different advertising frequencies. This is largely due to the lack of models and metrics to measure the effectiveness of advertising on the website.

While studies have concentrated on what is advertised and where it is advertised, none of the studies have focused on how advertising is presented and how that affects its efficacy. Studies on the efficiency of online advertising currently use accessible content rather than creating website content and advertising messages themselves, which results in a lack of objectivity and accuracy because the respondents may have previously heard of the advertisement and the brand. Therefore, in order to get more accurate results, it is really important to use a method that has better control over the responses from surveyors and to use a new model and metric for the research paper.

2. Literature review and Theoretical basis

Numerous studies on online advertising in general and the efficiency of online advertising on websites in particular have been conducted throughout the globe. However,

there is still no official research study available in Vietnam that examines the effects of geographic location, the volume of comparable advertisements, and the nature of online advertising on websites.

Effective research on internet advertising on websites all over the world has so far only looked at how the viewer's brand awareness is affected by the ad's location and status. The degree to which the content of the advertising and that of the website are identical has not been the subject of any official investigation. In studies on the quantity of advertisements, researchers mostly concentrate on the frequency of advertisements appearing in various formats, excluding websites.

Additionally, studies assessing brand awareness among viewers of internet advertisements have only utilized qualitative and quantitative techniques; no studies measuring brand awareness have employed experimental techniques, which has an impact on the objectivity and accuracy of the study findings. There have been several studies published since the 2000s, but with the development of the Internet today, viewers' perspectives have changed significantly, which has had an impact on their capacity to consume advertising information.

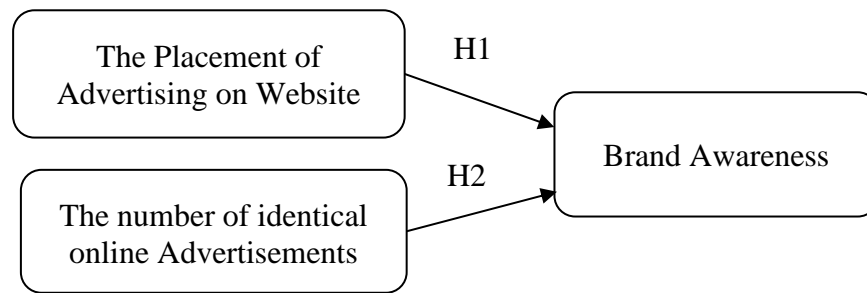

Brand awareness

Consumers' decision to buy a certain product or service is often based on their understanding of the brand. Brand awareness helps consumers decide which brand they will buy and where to buy it. Brand awareness reflects the ability of customers to recognize, distinguish, and name a brand under different conditions (Keller, 1993). Brand awareness includes brand recall and brand recognition.

Brand recognition

Brand recognition is understood as the ability of consumers to distinguish brands they have seen or heard of before (Keller, 1993). In other words, consumers have been exposed to the brand before, and when it comes to brand suggestions, they will recognize the brand. According to power theory, or threshold theory (Kintsch, 1970), recognition requires lower memory robustness than recall. Various studies have shown that people often choose things that are familiar to them (Coates et al., 2006; Hoyer & Brown, 1990; McDonald & Sharp, 2000), and at the same time, they are just looking at them without realizing it (Bornstein, 1989; Zajonc, 1968). Goldstein & Gigerenzer (2002) have shown that when the correct answer is unknown, people tend to choose answers they find familiar (Barreda, Bilgihan, Nusair, & Okumus, 2015) because they believe that the familiar answers are more reliable. Brand recognition is an equally important component of branding, explained by Lin (2009) as the consumer's perception of a brand through prior product experience plus known information. According to Aaker (1996), brand recognition is arguably more important for new brands or niche markets.

Research model

Hypotheses

H1: The placement of ads on the website has an impact on the viewer's brand awareness:

- H1a: Pop-up placement has a stronger impact on brand awareness than Banner placement.
- H1b: Pop-up placement has a stronger impact on brand awareness than Skyscraper placement.
- H1c: Banner placement has a stronger impact on brand recognition than Skyscraper placement.
- H1d: Banner placement has a stronger impact on brand awareness than Pop-up placement.
- H1e: Skyscraper placement has a stronger impact on brand awareness than Banner placement.
- H1f: Skyscraper placement has a stronger impact on brand awareness than Pop-up placement.

H2: The same number of ads has an effect on brand awareness.

- H2a: Three ad placements with the same content have a stronger effect on brand recognition than a single placement.
- H2b: One placement has a stronger effect on brand recognition than three placements with the same content.

3. Method

The study uses a combination of primary data collection methods, including survey, experiment and interview.

Survey

First, the authors viewed 100 websites in Vietnam to determine the ad placements and structures of the most popular ads. The authors then conducted a quantitative survey, asking 120 students in Hanoi to list five issues they are currently interested in to determine the topics that students are most concerned about today. This was done to choose the most representative website contents and advertising messages for the experimental research.

Experiment

The most commonly discussed topic (education, health, etc.) was then picked as the focus of the websites based on the poll results. The authors then created nine advertisements and eight websites to investigate the impact of brand awareness on viewers and the number of identical online advertisements. It compared the effects of different online advertising placements, including Banner, Skyscraper, and Pop-up ads, on viewers' brand recognition. It also highlighted the differences in impact between websites with three identical online advertisements. Each of the four stages of the investigation, which lasted two days and

included six shifts with ten interviews each, involved 264 individuals. 240 of the 264 participants' results were approved.

Table 1. Website conventions surveyed

Website	Placement of Advertising	Message of Advertising	Content of Website	Sample size
1	Banner	Entertainment	Entertainment	30
	Skyscraper	Food		
	Pop-up	Education		
2	Banner	Education	Entertainment	30
	Skyscraper	Entertainment		
	Pop-up	Food		
3	Banner	Food	Entertainment	30
	Skyscraper	Education		
	Pop-up	Entertainment		
4	Banner	Food	Education	30
	Skyscraper	Education		
	Pop-up	Entertainment		
5	Banner	Education	Education	30
	Skyscraper	Entertainment		
	Pop-up	Food		
6	Banner	Entertainment	Education	30
	Skyscraper	Food		
	Pop-up	Education		
7	Banner	Education	Health	30
	Skyscraper	Entertainment		
	Pop-up	Food		
8	Banner	Entertainment	Education	30
	Skyscraper	Entertainment		
	Pop-up	Entertainment		

The results of the experimental research were coded and analyzed using SPSS. The obtained results are a Chi-squared test with hypotheses H1 and H2 to test the impact of independent variables' placements and the number of identical online advertisements on brand awareness.

Interview: After the experiment, an in-depth interview was conducted to discover the causes and motives behind respondents' responses to experimental research, allowing for reliable findings of brand recognition through online advertising. Thirty-two respondents were chosen from eight groups and asked a series of questions based on their replies to learn more about the reasons behind the results, specifically why they recognized the brand image in the advertisement after surfing the website. The results show that the reasons why it is not brand awareness are frequently caused by respondents paying more attention to the Pop-up advertisements, causing respondents to miss information about the advertised brand, or by respondents overconcentrating on the website's content, etc. On the other hand, respondents have brand awareness because they can easily remember the ads when all the advertisements on the website are totally the same.

4. Results

4.1. Quantitative research results

After conducting a quantitative survey to determine the placement of advertising on websites and the areas of most interest today, the results show that Online advertising placements: The author's group collected 120 samples, and the results showed that there are three most popular placements for Online Advertising: Banner with 86/120 answers accounting for 71.7%; Skyscraper with 80/120 answers accounting for 66.7%; Pop-up with 87/120 answers accounting for 72.5%. Website content and advertising message: the topics "Education"; "Health" and "Entertainment" are the three most interesting topics, with 75/120 answers being "Education" accounting for 62.5%, 42/120 answers "Health" accounting for 35% and 84/120 answers "Entertainment" accounting for 70%. Therefore, the group selected the advertisement's message in 3 fields: Education; Health and Entertainment; and three fields for websites's content included: Entertainment and Education and Health; simultaneously, the advertising placements will be Banner; Skyscraper and Pop-up.

4.2. Chi-squared test analysis

In the analysis of the impact of ad placement on brand recognition, when comparing the impact of banner placement with skyscraper placement on entertainment-related advertising content, there are two variables: Recognizing the brand's promotional image and realizing the advertised brand name has Asymp coefficients. Sig. (two-sided) < 0.05, the rate of recognizing these two variables in the Banner placement is better than in the Skyscraper placement. For content related to the education sector, there is only one satisfying variable: Recognize advertised brand names with Asymp coefficients. Sig. (two-sided) < 0.05, the probability of recognizing this variable in the Banner placement is better than in the Skyscraper placement. This result shows the difference in effectiveness of Banner and Skyscraper placements, Banner ads are more effective than

Skyscraper ads in affecting image recognition, promotional image of the brand, and recognizing the advertised brand name.

When comparing the effects of Banner placement with Pop-up placement on educational-related advertising, there was one gratification: Realizing that the advertised brand name has Asymp coefficients. Sig. (two-sided) < 0.05. This result does not show a difference between the impact of Banner and Pop-up ad placement.

When comparing the impact of Skyscraper placements with Pop-up placements on entertainment-related advertising, there is a scale related to placement: Image recognition Branded promotional images have Asymp coefficients. Sig. (two-sided) < 0.05, the rate of recognizing this scale in the Pop-up placement is better than the Skyscraper Asymp coefficients placement. Sig. (two-sided) < 0.05 is the recognition of the brand's advertising image. This result shows the difference in the impact of Pop-up and Skyscraper ad placements. It can be seen that Pop-up ad placement has a stronger impact on the ability of Website viewers to recognize it than the Skyscraper advertising placement.

In the analysis of the impact of the number of ads with the same content on brand recognition, for banner ads, there are two satisfying scales: Brand recognition and Brand name recognition. advertised with Asymp coefficients. Sig. (two-sided) < 0.05, this recognition rate on websites with 3 identical ads is better than on websites with only 1 ad. For advertising in Skyscraper placements, there is a satisfying scale: Realize that the advertised brand name has Asymp coefficients. Sig. (two-sided) < 0.05, this recognition rate on websites with 3 identical ads is better than on websites with only 1 ad. For Pop-up ad placements, there are two satisfaction scales: Brand Ad Image Recognition and Advertised Brand Name Recognition with Asymp coefficients. Sig. (two-sided) < 0.05, this recognition rate on websites with 3 identical ads is better than on websites with only 1 ad. From this result, it can be seen that a Website with 3 identical ads is likely to have a stronger impact on the viewer's ability to recognize the Skyscraper ad placement.

Table 2. Results of Chi-squared test on brand awareness among Websites

		Names of variables	Asymp. Sig. (two sided)
Analyze the impact of the advertising placement factor on brand recognition	Comparison of the effectiveness of Banner and Skyscraper placements in the field of entertainment	Realize the advertising image of the brand	0.003
		Recognize the advertised brand name	0.032
	Comparing the effectiveness of Banner and Skyscraper placements in the field of education	Realize the advertising image of the brand	0.121
		Recognize the advertised brand name	0.015

		Names of variables	Asymp. Sig. (two sided)	
	Comparison of the effectiveness of Banner and Pop-up placements in the field of entertainment	Realize the advertising image of the brand	0.347	
		Recognize the advertised brand name	0.796	
	Comparing the effectiveness of Banner and Pop-up placements in the field of education	Realize the advertising image of the brand	0.598	
		Recognize the advertised brand name	0.032	
	Comparison of the effectiveness of Skyscraper and Pop-up placements in the field of entertainment	Realize the advertising image of the brand	0.035	
		Recognize the advertised brand name	0.058	
	Comparing the effectiveness of Skyscraper and Pop-up placements in the field of education	Realize the advertising image of the brand	0.039	
		Recognize the advertised brand name	0.754	
	Analyze the impact of the number of identical ads on brand recognition	Compare the impact of a website with 3 identical and a website with 1 ad in the Banner placement	Realize the advertising image of the brand	0.011
			Recognize the advertised brand name	0.001
Compare the impact of a website with 3 identical ads and a website with 1 ad in the Skyscraper placement		Realize the advertising image of the brand	0.519	
		Recognize the advertised brand name	0.01	
Compare the impact of a website with 3 identical ads and a website with 1 ad in the Pop-up placement		Realize the advertising image of the brand	0.037	
		Recognize the advertised brand name	0.035	

5. Discussion and Conclusion

5.1. Summary of research results

Regarding the placement of ads on the website that has an impact on the brand awareness of the viewers, research has shown that Pop-up ad placement has a stronger impact on brand recognition than the advertising placement. Skyscraper and Banner placement have a stronger impact on brand recognition than Skyscraper placement. *Therefore, hypotheses H1b and H1c are supported.*

Regarding the number of similar ads that affect brand awareness, the authors draw the conclusion that three ad placements with the same content have a stronger influence on brand recognition than a single ad placement. *Therefore, hypothesis H2a is supported.*

5.2. Discussing the results

First, both Banner and Pop-up placements have a stronger impact on brand recognition than Skyscraper placements. Specifically, for the ability to recognize the advertising image of the brand and recognize the advertised brand name, the Banner placement has a stronger impact than the Skyscraper placement for image recognition. When brand image is advertised, Banner placement has a stronger impact than Skyscraper placement. Through the qualitative interview conducted after the experiment, the reason given by the respondents for the Pop-up advertisement to have a stronger impact on the ability to recognize the advertising image is because the Pop-up advertisement is displayed. display in the center of the screen as the viewer reads the web page. Therefore, viewers are required to pay attention to the advertised brand image if they want to turn off this ad.

The reason why Banner ads have a stronger impact on brand names is because Banner ads are located right at the top of the website, right next to the website title, so the advertised image and brand name can be easily seen. closer. The fact that Skyscraper ads have a lower impact than the other 2 placements is also explained by the fact that this ad placement is located along the margins of the website, out of the viewer's eyes, so viewers will pay more attention to the website content. is to pay attention to advertising.

Second, for a website with three advertisements showing the same content, the ability to recognize the advertised brand image and the brand name is both high, compared to a website with only one ad placement. Specifically, for Banner and Pop-up advertising placements, the percentage of respondents who recognize the brand image and recognize the brand name advertised on the website with three advertisements with the same content is higher than that on the website alone. There is one advertisement showing that content. In addition, the website with three advertisement placements has a stronger impact on the viewer's ability to recognize the advertised brand name than the website with only one advertising placement at the Skyscraper placement. The reason for this problem is that the website has three ads with the same content, forcing viewers to constantly remember the advertising content. Meanwhile, for a website with only one ad placement, the number of times the viewer's recognition is lower; besides, there is other advertising content that interferes with the viewer's process of remembering the advertising content.

5.3. Recommendations and conclusions

From the above research results, the authors found that if the advertising purpose of the business is for viewers to recall the brand name or brand recognition, they can choose to advertise in the Banner or Pop-up placement instead of the Skyscraper location. However, to avoid the audience feeling uncomfortable because of the inconvenience and not wanting to receive the advertising message conveyed, the business should use the Banner placement. The reason is because of the psychology of avoiding advertising when viewers think that Pop-up ads are the most annoying and need to be turned off quickly (Le Wang, 2014) to view website content, so it often makes people uncomfortable.

The number of ads with the same content has a stronger impact on the brand recognition of the viewers than just one ad placement, this result is in agreement with Schmidt & Eisend (2015). Therefore, if businesses want to increase brand awareness, they can simultaneously use multiple ads with the same content appearing on the website at the same time instead of just one ad to increase the viewer's memory.

National Economics University, Hanoi, Vietnam

Abstract

The Industry 4.0 has strongly changed how business work all over the world, innovation is now becoming a must and everything related to innovation needs to be studied in detail. This study explores the factors that influence innovative work behavior among employees of startups in various industries, which are supported by the National Innovation Center. In this study, the factors analyzed included personal factors such as openness to experience, and intrinsic motivation, as well as organizational factors such as leader-member exchange, transformational leadership, and perceived organizational support. To achieve the research objectives, a survey of 213 employees and in-depth interviews with five employees were conducted. The findings of the study indicate that all factors mentioned above have an impact on innovative work behavior. The implications of these findings and practical recommendations proposed in this study can be used to design interventions that encourage and support innovative work behavior among employees, leading to improved organizational performance and competitiveness.

Keywords: *innovative work behavior, openness to experience, intrinsic motivation, leader-member exchange, transformational leadership, perceived organizational support.*

1. Introduction

Industry 4.0, with technologies like AI, Big data, virtual reality, and blockchain, is changing competitive advantages among economies. Thus, startups are considered key drivers to enhance entrepreneurial ecosystems in emerging economies (Getz and Robinson, 2003; Aftab et al., 2022). In that context, Vietnam has established the Vietnam National Center (NIC) to build an innovation ecosystem and pilot a regulatory environment for innovative activities.

Employee innovative behavior is crucial for an organization to achieve a competitive advantage in today's dynamic business environment (Yuan and Woodman, 2010). Innovative work behavior (IWB) has been shown to be a key driver of organizational innovation, which can result in improved performance and increased market share (Janssen, 2000).

Understanding the determinants of innovative work behavior is crucial for organizations to foster a workplace environment that cultivates and rewards creativity. According to Srirahayu and collaborators (2023), there are three innovative work behavior antecedents: personal factors, organizational factors, and external factors. However, choosing the right factors to analyze innovative work behavior is crucial. The factors of openness to experience, intrinsic motivation belonging to the group of personal factors and transformational leadership, leader-member exchange, and perceived organizational support to the organizational factors group are particularly relevant to this study based on its size and duration.

Openness to experience is a personality trait linked to an individual's behavior. Intrinsic motivation is the internal drive to engage in a behavior because it is interesting, enjoyable, or fulfilling in itself, and has been shown to be important for engaging in innovative work behavior. Leadership is also an important factor in innovative work behavior. Transformational leadership involves inspiring and motivating followers to achieve their full potential and has been positively associated with innovative work behavior. Leader-member exchange is also important for promoting innovative work behavior, as it refers to the quality of the relationship between a leader and their followers. Finally, perceived organizational support is important for creating a work environment that fosters innovative work behavior. When employees feel that the organization supports their ideas and values their contributions, they are more likely to engage in innovative work behavior.

This study will clarify how the above factors affect the innovative work behavior of employees working at startups supported by NIC. By understanding these factors, organizations can develop strategies to promote innovative work behavior and stay competitive in today's rapidly changing business environment.

The specific research objectives are as follows:

- Understanding the antecedents of innovative work behavior.
- Determining the factors affecting the IWB of employees and evaluating the IWB level of employees through the factors mentioned above.
- Identifying the barriers to IWB.
- Determining strategies that employees, leaders, organizations, and NIC can use to enhance IWB.

2. Theoretical Basic and Hypotheses

The OECD defines innovation as implementing new or improved products, processes, marketing, or organizational methods in business practices, workplace organization, or external relations (OECD, 2005). Innovative work behavior (IWB) refers to proactive employee behavior to generate, develop, and implement useful and valuable new ideas, processes, or products (Scott & Bruce, 1994). IWB includes both idea generation and implementation and is influenced by individual, organizational, and environmental factors (De Jong & Den Hartog, 2010). IWB is closely related to innovation, which refers to the process of creating and implementing new ideas, processes, or products that are novel,

useful, and valuable (West & Farr, 1990). IWB is considered a key antecedent of innovation, as it is the starting point for the innovation process and it is crucial for innovation, organizational learning, and adaptability (Janssen, 2000; De Jong & Den Hartog, 2010).

2.1. Openness to experience

Openness to experience (OTE) is a Big Five personality trait related to an individual's receptiveness to new ideas, experiences, and sensations (John et al., 2008). Research suggests that employees with high OTE are more creative and generate more innovative solutions (Scott & Bruce, 1994; Shalley & Gilson, 2004), possibly due to their imaginative, curious, and risk-taking nature (Amabile, 1983; Feist, 1998). Hiring and promoting individuals with high OTE may lead to improved organizational performance and competitive advantage through increased innovative work behavior (IWB) (Mumford et al., 1991), making it a valuable trait for organizations to consider when seeking to foster a culture of innovation. Then the following hypothesis is generated:

H1: There is a positive relationship between openness to experience and innovative work behavior.

2.2. Intrinsic motivation

Intrinsic motivation (IM) is a critical factor in driving innovative behavior in the workplace. It refers to the inherent desire to engage in an activity for its own sake, driven by personal satisfaction, enjoyment, or interest (Ryan & Deci, 2000). Amabile (1988) found that individuals who are more intrinsically motivated are more likely to engage in creative thinking and problem-solving, essential components of innovative behavior. Similarly, George and Zhou (2007) found that employees who are more intrinsically motivated are more likely to engage in proactive behavior, including innovative behavior such as generating new ideas and seeking out new opportunities. By promoting intrinsic motivation among employees, organizations may be able to encourage more innovative behavior and drive growth and success (Amabile, 1988; George & Zhou, 2007). Then the following hypothesis is generated:

H2: There is a positive relationship between intrinsic motivation and innovative work behavior.

2.3. Leader-Member Exchange

LMX theory highlights the importance of the leader-subordinate relationship in predicting work-related outcomes (Graen & Uhl-Bien, 1995). High-quality LMX is associated with positive employee outcomes such as job satisfaction, organizational commitment, and job performance (Liden et al., 1997). Studies have also shown a positive relationship between high-quality LMX and innovative work behavior and creativity (Jung et al., 2008; Wang et al., 2005). These findings suggest that organizations can promote innovative work behavior by fostering strong and supportive relationships between leaders and subordinates. Then the following hypothesis is generated:

H3: There is a positive relationship between LMX and innovative work behavior.

2.4. Transformational leadership

Transformational leadership (TL) is a leadership style that inspires and motivates followers to achieve their full potential and work towards a common goal that benefits the organization as a whole (Bass & Riggio, 2006). This leadership style has been linked to higher levels of job satisfaction, motivation, and commitment among employees.

In addition, research has shown that organizations that promote innovative work behavior are more likely to succeed in their industries (Shalley, Zhou, & Oldham, 2004). Transformational leaders can create a supportive work environment that empowers employees to take risks and try new things. This can lead to greater creativity and innovation among employees, as well as higher levels of engagement and commitment to the organization (Bass & Riggio, 2006).

Given the importance of innovative work behavior for organizational success, it is important to understand how leadership styles can impact employees' willingness and ability to engage in such behavior.

H4: There is a positive relationship between transformational leadership and innovative work behavior.

2.5. Perceived organizational support

Perceived organizational support (POS) refers to how much employees believe their organization values their contributions and cares about their well-being (Eisenberger et al., 1986). Research has found that POS is associated with job satisfaction, performance, and turnover intentions (Rhoades & Eisenberger, 2002). Employees who perceive high levels of organizational support may feel more comfortable taking risks and experimenting with new ideas, as they believe that their organization will reward their efforts (Scott-Ladd et al., 2006). Theories such as social exchange theory and self-determination theory explain the relationship between POS and innovative work behavior. In conclusion, promoting perceived organizational support is crucial for organizations that want to foster innovative work behavior (Eisenberger et al., 2010). Then the following hypothesis is generated:

H5: There is a positive relationship between perceived organizational support and innovative work behavior.

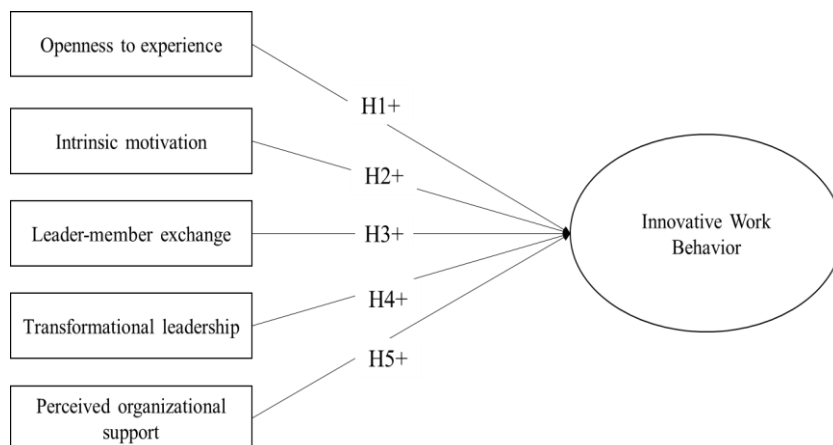

Figure 1. Theoretical research model

2. Method

This research used mix methods that included survey and indepth interviews. The questionnaire was distributed directly to 260 employees of startups at NIC, and there were 213 valid responses. After very result of survey, indepth interview with five persons were carried out to understand the insight of findings.

Measurement: variable Openness to experience (OTE) was measured by 8 items by Feist, G. J. (1998). Intrinsic motivation (IM) was measured by 5 items by Amabile TM. (1985). Leader-member exchange (LMX) was measured using 6 items developed by Graen, G. B., Novak, M. A., & Sommerkamp, P. (1982). Transformational leadership (TL) was measured using 7 items developed by Carless, S. A., Wearing, A. J., & Mann, L. (2000). Perceived organizational support (POS) was measured using 10 items adapted from Eisenberger, R., Huntington, R., Hutchison, S., & Sowa, D. (1986). The dependent variable is Innovative work behavior (IWB) was measured using 6 items developed by Scott, S. G., & Bruce, R. A. (1994).

All items were measured using a five-point Likert scale (with scores ranging from 1 = strongly not agree to 5 = strongly agree).

Table 1. Characteristics of the sample

Criteria		Number of observations	Percentage (%)
Sum		213	100
Gender	Female	92	43.2
	Male	107	50.2
	Not mentioned	14	6.6
Age	18 - 22	64	30.0
	23 - 30	95	44.6
	30 - 40	54	25.4
	More than 40	0	0.0
Education level	College	6	2.8
	University	182	85.4
	Master	19	8.9
	Doctor	2	0.9
	Others	4	1.9
Business age (years)	Less than 3 years	121	56.8
	3 - 5 years	59	27.7
	5 - 10 years	25	11.7
	More than 10 years	8	3.8
	Less than 10 people	15	7.0

Criteria		Number of observations	Percentage (%)
Number of employees in organization	10 - 20 people	115	54.0
	20 - 30 people	22	10.3
	More than 30 people	61	28.6
Industry sector	Technology	160	75.1

	Business	9	4.2
	Manufacturing	6	2.8
	Healthcare	3	1.4
	Others	30	14.1

Source: The author's research

The surveyor obtained 213 valid responses. The demographics of the respondents were as follows: 50.2% were male, 44.6% were 23 - 30 years old, and 85.4% of the employees surveyed had a university degree. 56.8% of employees participating in this survey belong to enterprises operating for less than 3 years, with a scale of 10 to 20 people (54%) and owners and technology-related areas (75.1%).

4. Results

4.1. Exploratory factor analysis (EFA)

Table 2. Exploratory analysis and the reliability of the scale

Factors	Items	Factors loading				Mean	Std. Dev.
Openness to experience (Cronbach's alpha = 0.948)							
OTE1	I enjoy trying new things and experiences.	0.935				4.11	0.779
OTE7	I enjoy creative and imaginative activities.	0.895				4.02	0.798
OTE4	I enjoy discussing abstract ideas and concepts.	0.885				4.06	0.799
OTE2	I often seek out new and challenging experiences.	0.878				4.02	0.818
OTE3	I am open to new ideas and ways of thinking.	0.821				4.10	0.780
OTE8	I am willing to take risks in order to achieve my goals.	0.804				4.10	0.800
OTE5	I am willing to consider alternative perspectives and viewpoints.	0.774				4.07	0.774

Factors	Items	Factors loading					Mean	Std. Dev.
OTE6	I am comfortable with uncertainty and ambiguity.	0.766					4.05	0.862
Perceived organizational support (Cronbach's alpha = 0.909)								
POS8	My organization fosters a positive work environment and culture.		0.79 2				4.17	0.854
POS7	My organization shows a sincere interest in my concerns and opinions.		0.78 5				3.94	.0920
POS5	My organization treats employees fairly and respectfully.		0.70 9				4.08	0.785
POS10	My organization provides opportunities for employees to participate in decision-making.		0.70 2				4.01	0.871
POS1	My organization values my contributions to the workplace.		0.70 1				3.97	0.776
POS2	My organization cares about my well-being and job satisfaction.		0.69 7				3.98	0.771
POS9	My organization communicates clearly and openly with employees.		0.68 4				4.03	0.921
POS4	My organization recognizes my efforts and achievements at work.		0.66 6				3.99	0.833
POS6	My organization supports my career development and growth.		0.66 0				4.11	0.760
POS3	My organization provides the resources necessary to perform my job effectively.		0.60 4				4.06	0.901
Transformational leadership (Cronbach's alpha = 0.890)								
TL3	My leader gives encouragement and recognition to staff.			0.83 7			4.10	0.884
TL4	My leader fosters trust, involvement, and cooperation among team members.			0.82 9			4.08	0.875
TL7	My leader instills pride and respect in others and inspires me by being highly competent.			0.82 5			4.06	0.912

Factors	Items	Factors loading					Mean	Std. Dev.
TL1	My leader communicates a clear and positive vision of the future.			0.803			4.10	0.857
TL6	My leader is clear about his/her values and practices what he/she preaches.			0.630			3.99	0.916
TL2	My leader treats staff as individuals, supports and encourages their development.			0.537			3.91	0.858
TL5	My leader encourages thinking about problems in new ways and questions assumptions.			0.533			3.99	0.961
Intrinsic motivation (Cronbach's alpha = 0.898)								
IM4	I enjoy creating new procedures for work tasks.				0.962		3.81	0.933
IM2	I enjoy coming up with new ideas for products.				0.950		3.84	0.943
IM3	I enjoy engaging in analytical thinking.				0.950		3.83	0.933
IM1	I enjoy finding solutions to complex problems.				0.622		4.09	0.781
IM5	I enjoy improving existing processes or products.				0.595		4.16	0.845
Leader-member exchange (Cronbach's alpha = 0.790)								
LMX6	I have a highly effective working relationship with my supervisor.					0.753	3.92	0.766
LMX5	I have enough confidence in my supervisor that I would defend and justify his/her decision if he/she were not present to do so.					0.723	3.96	0.928
LMX4	My supervisor uses his/her power to help me solve problems in my work.					0.685	3.97	0.895
LMX3	My supervisor recognizes my potential.					0.676	3.98	0.743
LMX2	My supervisor understands my job problems and needs.					0.665	3.96	0.837

Factors	Items	Factors loading					Mean	Std. Dev.
LMX1	I know how satisfied my supervisor is with what I do.					0.617	3.89	0.834
Innovative work behavior (Cronbach's alpha = 0.742)								
IWB1	I search out new technologies, processes, techniques, and/or product ideas.	0.727					4.06	0.796
IWB2	I come up with innovative and creative ideas.	0.723					4.24	0.821
IWB4	I investigate and secure funds needed to implement new ideas.	0.712					4.08	0.875
IWB5	I develop adequate plans and schedules for the implementation of new ideas.	0.701					4.09	0.787
IWB3	I promote and champion ideas to others.	0.666					3.97	0.921
IWB6	I consider myself a creative member of my team.	0.589					4.11	0.760

Source: The author's research

Exploratory factor analysis was conducted by the Principal component extraction method and Varimax rotation separately for independent and dependent variables. The analysis explained 63.42% of the variability of the independent variables and 69.45% of the variability of the dependent variables, meeting the test conditions. Observable variables with a factor loading value greater than 0.5 show the correlation value between the observed variables of that factor. The loading coefficients are all greater than 0.5, indicating good statistical significance for the observed variables. The obtained KMO coefficient is 0.859, showing the overall correlation between the observed variables in the study. Cronbach's Alpha indexes were all above 0.7, indicating good reliability of the scale.

4.2. Correlation analysis

The correlation analysis reveals that the independent variables are significantly related to the dependent variable, with the perceived organizational support factor showing the strongest correlation (correlation coefficient 0.740) followed by transformational leadership (correlation coefficient 0.7). All hypotheses are supported, particularly hypotheses H5 and H4. The average ratings for leader-member exchange and intrinsic motivation were low, with mean values of 3.94 and 3.95, respectively, while innovative work behavior had the highest mean value of 4.09. The remaining factors were rated at an average level of around 4.04.

Table 3. The Mean and Correlation analysis

Independent variables	Mean	Std. Dev.	1	2	3	4	5
1. Openness to experience	4.07	0.687					
2. Intrinsic motivation	3.95	0.749	0.230**				
3. Leader-member exchange	3.94	0.584	0.037	0.040			
4. Transformational leadership	4.05	0.686	0.205**	0.195**	0.192**		
5. Perceived organizational support	4.01	0.624	0.271**	0.209**	0.277**	0.597**	
6. Innovative work behavior	4.09	0.496	0.477**	0.410**	0.401**	0.700**	0.740**

**Correlation is significant at the 0.01 level (2-tailed).

4.3. Linear regression

Table 4. Estimation results of the model

Model Summary ^b								
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	R Square Change	F Change	Sig. F Change	Durbin-Watson
1	0.896 ^a	0.803	0.798	0.22300	0.803	68.256	0.000	1.548

Predictors: (Constant), POS, IM, LMX, OTE, TL_a
 Dependent Variable: IWB_b

Source: The author's research

R Square = 0.803, so the independent variables in the model explained 80.3% for the variation of the innovation behavior variable in the work of employees. This is a good result for this research model. The VIF index (variance inflation factor) to measure the influence of multicollinearity, the VIF index of the data ranges from 1,089 to 1,698, within the acceptable range (Hair et al., 2019), shows that multicollinearity does not affect the results.

Table 5. The results of analysis of variance ANOVA

ANOVA ^a						
Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	41.835	5	8.367	68.256	0.000 ^b
	Residual	10.294	208	0.050		
	Total	52.129	213			

a. Dependent Variable: IWB
 b. Predictors: (Constant), POS, IM, LMX, OTE, TL

Source: The author's research

Regression results show that the Sig coefficients of all independent variables in the model are less than 0.01, so it can be concluded that they all have an impact on employees' innovation behavior at work. Thus, the results of the study accept all hypotheses. To test the fit of the population scale model, the researcher considered the F value from the ANOVA analysis table, the F value = 68.256, the Sig value. = 0.000b, so the linear regression model is suitable for the data set and can be used.

Table 6. Regression coefficient model of factors affecting innovative work behavior of employees

Coefficients ^a								
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		B	Std. Error	Beta			Tolerance	VIF
1	(Constant)	-0.074	0.157		-.476	0.635		
	OTE	0.183	0.024	0.253	7.736	0.000	0.892	1.121
	IM	0.132	0.021	0.200	6.210	0.000	0.918	1.089
	LMX	0.184	0.027	0.217	6.730	0.000	0.920	1.087
	TL	0.256	0.028	0.355	9.180	0.000	0.637	1.569
	POS	0.284	0.032	0.357	8.876	0.000	0.589	1.698

a. Dependent Variable: IWB

Source: The author's research

The relationship between the dependent variable and the independent variables is shown in the following linear regression equation:

$$IWB = 0.284 * POS + 0.256 * TL + 0.184 * LMX + 0.183 * OTE + 0.132 * IM - 0.074$$

5. Discussion and Conclusion

5.1. Discussion

Perceived organizational support (POS) has a positive effect on IWB, consistent with Zhang et al. (2018). When asked about the reasons for their scores in this section, four out of five participants in the in-depth interview answered that their organization is very small, each person has a large workload, and the leader is under significant pressure. Therefore, the leaders' concern for some of the employees' personal problems (personal development, job satisfaction, and well-being) is reduced. Additionally, the lack of financial resources or inadequate financial allocation in startups is insufficient to support the individual needs of everyone. One participant stated that the company cares about the needs of employees, but the level of attention is not sufficient. The employees need to be asked more about job satisfaction, and the company should survey employee feedback more often.

Transformational leadership (TL) has a positive effect on IWB, consistent with Wang et al. (2019) and Kim et al. (2016). In-depth interviews revealed that some leaders

prioritize meeting deadlines over employee development. However, the TL2 factor - “My leader treats staff as individuals, supports and encourages their development” had an average score below 4. An interviewee mentioned that his leader was more focused on achieving tasks and meeting deadlines, and they may not prioritize staff development as much as they should.

Leader-member exchange (LMX) has a positive effect on IWB, consistent with Jiang et al. (2019). However, the average assessment of LMX factors was less than 4, indicating ineffective or insufficient communication between leaders and employees. One reason for this may be that leaders have not invested enough time or effort in building positive relationships with their followers, given the significant workload placed on leaders of startup companies. Another reason mentioned in the in-depth interviews for the low scores on LMX is a lack of fit between leaders and their followers. As leaders are often talented people invited from abroad with different educational and cultural backgrounds compared to employees, this can result in a communication gap.

Openness to experience (OTE) has a positive effect on IWB, consistent with De Jong and Den Hartog (2007). The factor had a high mean score, indicating that employees possess creativity, dynamism, and a willingness to take risks that contribute greatly to startup businesses.

Intrinsic motivation (IM) has a positive effect on IWB, consistent with Deci and Ryan (1985), Gong et al. (2013), and Karwowski et al. (2019). However, some variables related to motivation for generating new ideas and implementing innovative behavior had average scores below 4. In-depth interviews revealed that employees feel insufficiently supported by enterprises for example, they have no acknowledgment of the direction of the leader and the business, which leads to employees’ lacking autonomy, control over their work, and confidence in their abilities.

5.2. Recommendations for startups at NIC

In-depth interviews with employees have revealed that they want attention not only on work-related issues but also on personal development, satisfaction, well-being, and transparency of their businesses. To improve these issues, organizations can consider the following suggestions: Organizations should build effective communication traffic between employees and leaders as communication that is timely, informative, and relevant can foster a sense of trust and openness between employees and leaders, leading to greater job satisfaction and motivation, and it does not have to come at a high cost. Organizations should set specific development goals that align with company objectives to provide a sense of purpose and commitment. Research by Zhao et al. (2017) has shown that employees who are given specific, challenging goals are more motivated and perform better. Businesses should develop criteria to evaluate employee dedication and recognize and reward that dedication. When employees feel valued and appreciated for their work, they are more likely to be motivated and dedicated to their future activities (Gifford, Zammuto, and Goodman, 2019).

5.3. Recommendation for NIC

NIC, as a state agency supporting the innovation ecosystem in Vietnam, should take action to create an environment that encourages innovative work behavior. This includes

investing in R&D to fund basic and applied research and development projects to overcome the high costs and risks of innovation for enterprises (Liu, 2020) thereby, helping start-up businesses have funds for employee support activities. NIC should also supplement and adjust incentives specified in Decree 94/2020/ND-CP to adapt to societal and global trends, establish policies and regulations that encourage socially responsible practices, and organize activities to promote collaboration between businesses, universities, and research institutions to foster innovation and at the same time, recruit human resources for innovation (Burchell et al., 2020; Koivisto & Lipponen, 2019).

5.4. Conclusion

The study found that organizational support and leadership are crucial for fostering innovative work behavior. By focusing on factors such as effective communication, specific development goals, and criteria for evaluating employee dedication, organizations can foster an innovative workforce. Although the study has limitations, such as small sample size and limited scope, it can still guide organizations seeking to create an environment that enhances innovation and empowers their employees to be creative, proactive, and adaptable. Future research could explore a broader range of factors in addition to the factors mentioned in this study or focus on the perceived organizational support and transformational leadership factors, as well as examine the innovative work behavior in other industry sectors.

Abstract

This paper seeks to investigate and analyze digital transformation readiness-related factors among employees of small and medium-sized enterprises. To accomplish the research objective, exploratory factor analysis and descriptive statistical analysis were employed. The survey of 208 employees residing and working in Hanoi, one of the cities with the most active digital transformation activities in Vietnam, yielded the collected data. In-depth interviews were also used to gain a more comprehensive understanding of employees' readiness for digital transformation. Research results show that: (i) there are significant differences in readiness for digital transformation between employees of different ages, sectors of operation, and professional qualifications; (ii) readiness-related factors, including self-efficacy, attitude, characteristics of employee, leadership, perceived benefits and perceived risks were derived from the exploratory factor analysis; (iii) while the majority of employees comprehend the benefits of digital transformation and have a positive attitude toward it, some lack confidence in their own abilities, and have not yet fully felt the risks and support of their leaders in this process. From the research findings, some implications have been proposed.

Key words: *digital transformation, SMEs, readiness*

1. Introduction

Alongside the emergence of the Fourth Industrial Revolution in recent years, the digital transformation trend is gaining momentum in the majority of countries around the globe, significantly enhancing the efficiency of organizations. Digital transformation enables businesses, particularly small and medium-sized businesses, to achieve greater efficiency and flexibility, optimize production processes, and create value propositions

and timely responses to market requirements. (Alcacer & Cruz-Machado, 2019; Queiroz et al., 2020; Chen et al., 2018; Dedehayir et al., 2017). In addition, digital transformation is required to maintain market competitiveness and technological leadership. (Rachinger et al., 2019).

To achieve digital transformation success, it is necessary to emphasize the importance of employees. People play a central role in lean philosophy activities that create value, reduce waste, and continuously improve. Such processes significantly rely on employee engagement and participation in problem solving and learning (Liker, 2004; Slack et al., 2010; Womack et al., 1990). However, digital transformation can create new problems and cause anxiety and tension among employees. Research by Vakola et al. (2004) confirms that employees may experience apprehension and resistance if they are unaware of upcoming changes and their potential effects. In contrast, organizational trust, the leader's achievement vision, and charisma will result in a degree of change acquiescence. Digital transformation drastically alters production methods, necessitating a production force with synchronized qualifications and awareness in order to deploy, coordinate, and implement the economy effectively. In industries where technology can replace humans, jobs will be lost, but new opportunities will be created in industries that require both advanced technology and a skilled workforce. This will impact the structure of jobs and the labor market, resulting in significant changes and posing numerous challenges for employees and the labor market as a whole. Also, there are significant concerns that it may be difficult for organizations and workers to adapt to digital transformation and reap its benefits.

By the end of 2021, Vietnam had approximately 850,000 active businesses, of which 96% were small and medium-sized and only 4% were medium and large (Bich Ngan, 2021). Most enterprises have initially applied software and solutions for sales management, online sales, omni-channel marketing, customer relationship management, and distribution channel management. However, many businesses find it difficult to engage employees in the planning, implementation, and application of digital at work, which determines the success of the business in the process of digital transformation. determine how to prepare employees for transformation. Consequently, capturing employees' readiness for timely and appropriate solutions will aid in achieving the transition objective. The digital transformation of businesses is more convenient and simpler to implement, particularly for small and medium-sized businesses (SMEs) with limited resources.

2. Literature review and Theoretical Basic

2.1. Literature review

Kempers (2023) conducted a study on the driving and limiting factors for employees in digital transformation in small and medium-sized enterprises (SMEs). This study was carried out using the development service network of businesses in the Netherlands. The authors used a semi-structured interview method with open-ended questions to gain an overall understanding and discuss the process with employees. During the interviews, the interviewer not only asked prepared questions but also asked spontaneous questions. By

doing so, the authors gained new insights (Huberman & Miles, 1994). Interviewees were introduced and explained in advance to have a better understanding of digital transformation and how they responded. The collected data was analyzed and compared with existing literature to form an action strategy on how SMEs in the service sector can improve the current situation by applying digital transformation. Finally, the study results identified several important factors influencing employee readiness, such as skills, leadership, and their participation in digital transformation.

Wen and Atan (2021) in their study, "SMEs Readiness Towards Digital Transformation in Malaysia," addressed five aspects that influence the process of a company's digital transformation. One of these aspects was the readiness of employees. The researchers used descriptive analysis and non-randomized sampling methods. The authors also used quantitative methods to clarify issues by creating numerical data or data to make the data more meaningful. Then, a questionnaire was distributed through an online platform, Google Form, as a research tool to collect data from SMEs in Perak's manufacturing sector. Finally, the authors concluded that employee readiness is an extremely important factor in driving a company's readiness for digital transformation.

Nguyen (2021) study on "Barriers to Digital Transformation for SMEs in Vietnam" emphasized the key role of human resources, especially the extent to which employees participate in digital transformation. Besides using the network modeling method SEM, the author also studied and analyzed documents, including books, newspapers, magazines, reports, and local and foreign studies related to barriers to digital transformation. The author surveyed SMEs through questionnaires and obtained 228 valid responses for the study. Finally, the author made observations about the role of human resources in digital transformation and proposed solutions to promote successful digital transformation in companies.

Giang et al. (2022), in their study "Readiness of SMEs to Apply Big Data: An Experiment in Vietnam," pointed out that there must be employee readiness in terms of perception and knowledge in using big data in digital transformation. The researchers surveyed businesses through questionnaires, and 274 valid questionnaires were used for analysis. The data was analyzed using STATISTICA to present descriptive statistics, correlation analysis, and reliability testing of measured factors. The study concluded that mainly small and medium-sized businesses have not successfully applied digital transformation because they are not ready in terms of human resources, and therefore, more investment is needed in human resources.

Ates and Acur (2022) conducted a study on the impacts of digital readiness and changing outdated methods in small and medium-sized high-tech enterprises headquartered in the UK. The authors applied a qualitative, longitudinal approach with a total of 22 structured direct interviews. All data was uploaded to the database using NVIVO 11 Pro software for the purpose of coding. Finally, the study concluded that in order to successfully digitize SMEs, in addition to technological factors, changes in the external work environment and work habits of both leaders and employees are also necessary. This has

significant implications for ensuring that the digitization process is implemented effectively and successfully within the business.

Rafiah et al. (2022) argued that "In addition to technology, automation, processes, and strategy, human resources are one of the most important considerations for companies, especially small and medium-sized enterprises, when implementing digitization in their businesses." The study used a definition of digital readiness along with a descriptive survey research method as a measure that can be used to assess the readiness of entrepreneurs for digital transformation, particularly in West Java (Indonesia). Data was collected through a survey using a questionnaire distributed to various small and medium-sized enterprises in West Java.

Volker Sticha et al. (2020), in their study "Measures for a successful Digital Transformation of SMEs", concluded that the adaptability and capability of the workforce is one of the important factors that contribute to the success of the digital transformation process. The authors used the case study research method of EISENHARDT along with a theoretical sampling method to select cases for the study, which included 30 supported small and medium-sized enterprises.

2.2. Theoretical Basic

Based on the theory of technology acceptance model (TAM) and the theory of extended planned behavior (TPB), the surveyed and analyzed factors are included. In order to incorporate them in the analysis, the original factors in these models were modified to correspond with the context of digital transformation and contrasted with recent factors from the literature review and preliminary interview results. As a consequence, the analysis included the seven factors listed below:

Table 1. Factors and measure scales.

No.	Factor	Number of initial items	Adapt from
1	Attitude (AT)	4	Davis (1989)
2	Characteristics of employee (CE)	5	Caldwell and Liu (2011)
3	Self- efficiency (SE)	5	Holt et al (2007)
4	Leadership (LD)	4	Marijana Rodić, Slobodan Marić (2020)
5	Perceived benefits (PB)	4	Davis (1989)
6	Perceived risk (PR)	5	Michael & Chen (2022)
7	Readiness to digital transformation (RT)	4	Holt et al (2007)

Source: Research team's synthesis

Attitude: Attitude is the expression through words, gestures, and actions about objects, phenomena, and people through valuable evaluations, including cognition,

influence, and behavior. Attitude can be positive or negative in external expressions of the person who expresses it. The Theory of Planned Behavior (TPB) emphasizes that attitude leads to behavior. This means the direct participant's evaluation of the results they obtained when doing activities in digital transformation, more generally than just the degree of positive or negative evaluation of this behavior. If the employees have a positive attitude towards digital transformation, it will increase their readiness for digital transformation.

Characteristics of Employee: This factor can be examined from various perspectives. In this study, employee characteristics refer to the employee's innovativeness and whether the employee exhibits more features of innovators or adopters. People who are innovative are typically risk-takers, youthful, content with their socioeconomic standing, sociable, and interested in digital transformation changes. Their risk tolerance induces them to adopt technologies even when they may ultimately fail (Rogers, 2003; Jin, 2013).

Self-Efficacy: The confidence in one's ability to perform digital transformation tasks is another crucial factor. The belief that one can easily perform new tasks reflects employees' readiness for change. Employees who believe that they have the necessary skills, or are willing to learn them, are more likely to be ready for change. Confidence in one's ability to perform new tasks is often considered a critical factor in successful change management. Berneth (2004) argues that assessing one's own abilities is essential for successful transformation.

Leadership: This element reflects an individual's perception of leadership support for organizational change. Members of the organization will be more open to change if they perceive the backing of the organization's most senior leaders. This support is manifested itself through communication, encouragement, assisting employees adjust to change, or commitments to change from senior managers. According to Ngereja et al. (2020), the commitment of top leadership plays a vital role and can be considered a foundation for other factors to exist. Therefore, leadership support is required for employees to comprehend that digital transformation is necessary and beneficial to the organization.

Leadership: This element reflects an individual's perception of leadership support for organizational change. Members of the organization will be more open to change if they perceive the backing of the organization's most senior leaders. This support is manifested itself through communication, encouragement, assisting employees adjust to change, or commitments to change from senior managers. According to Ngereja et al. (2020), the commitment of top leadership plays a vital role and can be considered a foundation for other factors to exist. Therefore, leadership support is required for employees to comprehend that digital transformation is necessary and beneficial to the organization.

Perceived benefits: This factor reflects the values that individuals receive if changes occur in the organization. Employees can receive values in terms of time (work efficiency), finance (salary), customer satisfaction, etc. Clearly understanding the benefits received can improve the readiness level of employees for digital transformation because "If individuals do not believe that change is beneficial to them, they are unlikely to have an overall positive readiness assessment" (Armenaski and Haris (1999)).

Perceived risk: Employees may worry about their job prospects or feel uncertain about the skills and knowledge required for the digital transformation. These concerns can significantly impact their readiness for change. The perception of risks and difficulties associated with digital transformation, such as changes in salary, job responsibilities, skills, and adaptability, are important considerations for employees. This factor includes five questions that measure employees' awareness of the risks and difficulties they may encounter.

Readiness: According to the studies by Armenakis (1993) and Holt et al. (2007), readiness for change is one of the most important factors related to employee support for change initiatives. When employees are receptive for change or willing to participate in digital transformation, the process of digital transformation within a business will be smoother. . This perception is manifested through an individual's perception of their adaptability and the benefits that digital transformation brings to them personally and the company in general. When this perception is correct, it also reflects their readiness for digital transformation.

3. Method

3.1. Research Method

The research team utilized both qualitative and quantitative research methods. Personal interviews are used for qualitative research to achieve two goals: (1) to explore readiness-related factors and compare their applicability to the theoretical foundation before conducting quantitative survey; and (2) to gain a more comprehensive understanding of employees' readiness for digital transformation. The quantitative research method was conducted through a survey of 208 employees in Hanoi. Stratified random sampling and snowball sampling were employed as sampling techniques. Based on the structure of Hanoi's small and medium-sized businesses, the research team selected employees from corresponding businesses and asked respondents to recommend survey subjects from other businesses.

3.2. Data collection and analysis

Data was collected from December 2022 to January 2023. The study's questionnaire was founded on previous research. Some questions were modified to fit the context and characteristics of Hanoi's small and medium-sized enterprises. Through in-depth interviews with a number of specialists, leaders, and employees, the author modified the measurement scales. On the basis of the findings from the in-depth interviews, the opinions were modified to reflect the ideas and language of the research subjects. Several new viewpoints were formulated and incorporated into the measurement scales. This study employed a 5-point Likert scale, with 1 representing "strongly disagree" and 5 representing "strongly agree." The formal study was conducted after the questionnaire was modified through pilot interviews to ensure textual coherence.

The research team distributed an online questionnaire to personnel who had participated in digital transformation. 235 responses were received by the research team. Only 208 samples were used for analysis after invalid questionnaires were removed. SPSS software was used to input and process the questionnaires. The measurement scale for individual readiness for organizational change was filtered using the Cronbach's Alpha reliability coefficient and exploratory factor analysis (EFA).

4. Results

4.1. Demographic characteristics

The demographic characteristics of the participants in this study include their gender, age, job sector, level of education and digital technology expertise. The survey showed that the gender distribution of the participants was relatively even, with 48% female and 52% male. The majority of respondents were between the ages of 18 and 24 (44%), followed by those between the ages of 25 and 34 (34%) and those between the ages of 35 and 44 (17%). The group of employees aged 45 to 60 comprised the smallest proportion, accounting for only 5% of those surveyed. Regarding the educational level of the respondents, there was a diverse distribution. The majority of respondents reported having a university degree (78%), followed by master's degree (11%), vocational college level (9%) and finally high school diploma (2%).

Figure 1. Age, gender and education level

Source: Research team

Among the survey participants, 40% worked in the commercial sector, followed by the construction industry with 18%, the transportation and logistics industry with 16%, and the education sector with approximately the same percentage, 15%. Only 10% of those surveyed were employed in the information technology industry, while only 2% were employed in the agriculture-forestry-fishery industry. In terms of digital transformation expertise, the majority mainly used utilities from the internet and social networking access (49%). 31% of individuals whose occupations are related to digital technology did not graduate from relevant majors, while 20% of individuals graduated from relevant digital technology majors.

Figure 2. Ownership and technology level

Source: Research team

4.2. Employee digital transformation readiness by different demographic groups

Different demographic groups have variable levels of employee readiness for the digital transformation, according to the survey conducted by the research team.

Readiness by age

Figure 3. Readiness of SMEs employees by age

Source: Research team

Based on the survey results of the research team, there are differences between age groups and a tendency for readiness to decrease with age. The percentage of young employees participating in the survey is quite high and they tend to adapt to new technology and enjoy challenging themselves. Employees in the three age groups between 18 and 44 generally have comparable levels of readiness, scoring 4.18, 4.11 and 4.08 out of a possible 5 points, respectively. For those aged 45 to 60, adapting to digital transformation remains challenging, so their readiness level is still low

Readiness by gender

Figure 4. Readiness of SMEs employees by gender

Source: Research team

In terms of gender, male employees have a readiness level of 4.06 out of five while female employees have a readiness level of 4.02 out of five. Overall, there is an indifference between the readiness levels of men and women overall. Some studies suggest that men have a more positive attitude towards digital technology and are more willing to access and use new technologies than women. However, personal perception and skills also play a role in this difference. If women have good knowledge about digital transformation, they will be willing to embrace it like men. Therefore, all employees, regardless of gender, need to be supported in their training, as digital transformation and readiness for digital transformation are necessary for all employees.

Readiness by sector of operation

Figure 5. Readiness of SMEs employees by sector of operation

Source: Research team

Employees in all industries have a readiness level of four or higher, which is greater than the industry average. Agriculture, forestry, and aquaculture industries achieved the lowest score (3.92), which is lower than the overall result for the entire industry. Although the demand for technology applications in production in this industry is increasing, the readiness level of employees is still low. This may be due to the fact that this field has not yet developed many advanced technologies, and the majority of its work is still performed manually. It can be said that employees in this industry are accustomed to working without new technologies, making digital transformation difficult for them to adapt to. The IT industry ranks first with a readiness level of 4.17 out of 5 points. This is completely consistent with reality, as employees in this industry regularly access technology applications and intelligent devices, so they feel very ready to participate in digital transformation. Next are industries such as transportation-logistics (4.13), industry-construction (4.07), education (4.06) and commerce (4.02).

Readiness by form of bussiness ownership

According to the survey results, employees in different types of enterprises have a readiness level of around 4 points. Overall, there is little disparity in readiness levels between

different types of enterprises. Corporations and partnerships rank first and second with a small difference (4.02 and 3.98, respectively). Private enterprises have the lowest score of 3.91, which is lower than the overall score for all industries (3.97/5).

Figure 6. Readiness of SME employees by form of business ownership

Source: Research team

Readiness by professional qualifications

Employees who graduated from technology-related fields show a higher level of readiness for digital transformation, scoring 4.05/5, which is consistent with the reality. A group of employees in the information technology industry stated, "We frequently apply technology to work and other activities, so we do not feel this is a big challenge." Next are employees who did not graduate from technology-related fields but whose jobs involve digital technology, scoring 4.01/5, which is comparable to the previous group. Finally, employees who mainly use utilities like internet access and social networks score around 3.84/5.

Figure 7. Readiness of SME employees by professional qualifications

Source: Research team

4.3. Employees' assessment on readiness-related factors

EFA Analysis - Evaluation of the Scale

The Kaiser-Meyer-Olkin (KMO) and Bartlett tests were utilized to determine whether factor analysis was suitable for the set of propositions. The Cronbach alpha coefficient and exploratory factor analysis (EFA) are utilized to determine the dependability of each structure. All of the investigated structures satisfy the requirements for internal consistency and unidirectional proportionality, as demonstrated by the findings. The item-total correlation of each construct's items is greater than 0.3. All KMO coefficients are greater than 0.5, the p value (Bartlett test) is 0.05, the total explanatory variance is greater than 50%, and the loading coefficients of the items in each structure are all greater than 0.5 (Table 2). The fundamental established factors are identical to those in the original research model; only undesirable variables will be eliminated.

Table 2. Reliability of each factor (n = 208)

Factor	Number of Items	Cronbach's Alpha	Corrected-item total correlation minimum	KMO	p-value	Factor loading minimum	TVE (%)
Attitude	4	0.882	0.694	0.806	0.000	0.648	73.749

Key findings from the survey and in-depth interviews

After factor analysis and reliability testing of the scale, the employees' perceptions of the factors are examined. Using a combination of survey and in-depth interview data, a more comprehensive picture of employees' readiness for digital transformation is drawn up.

Table 3. SMEs employees' assessment on readiness and related factors

Source: Research team

Attitude: Employees have a very positive outlook on digital transformation. With a rating of 4.1, it shows that the majority of them perceive digital transformation as useful and necessary. Although there are risks associated with digital transformation, overall, the benefits outweigh them. This is a good sign that encourages the readiness of employees to embrace digital transformation.

An office female employee stated: *"When we weigh the pros and cons, the benefits are still greater, and it's important to adapt and embrace it."*

Similarly, an engineer expressed: *"Adapting to digital transformation is necessary to leverage its benefits and, at the same time, avoid potential risks in the future."*

Characteristics of employees: Most employees have an objective view of digital transformation due to their openness and enthusiasm for new experiences. This aspect has a relatively high impact on employees' readiness, with a score of 4.065 out of 5. The survey sample of the study focuses primarily on workers aged 18-35 who have an open mindset and are willing to adapt to digital transformation.

During an interview, an engineer shared his opinion to reveal the personality traits of a young person with awareness of digital transformation, as follows: *"Currently, the world is rapidly moving from the industrial age to the digital age. This is creating a significant difference in the operation and production methods of economic sectors worldwide. Adapting to digital transformation is essential to take advantage of its benefits and avoid potential risks in the future."*

Self-efficacy: Overall, the "self-confidence in personal capabilities" aspect of employees has a significant impact on their readiness to adapt to digital transformation, with an average score of 3.806 out of a total of 5 points. Most employees feel that the ongoing digital transformation is reasonable for the development of the times because technology is continuously advancing and requiring employees to have the necessary technical skills to work. A Viettel employee expressed their opinion in an interview, saying, *"Artificial intelligence is thriving, and digital transformation is a means to demonstrate that." Digital transformation influences employees, making it easy for them to complete their work, so employees expect digital transformation to continue to exist in the present and future.* However, employees who lack technical skills and good knowledge of digital technology may feel less ready to apply and perform various tasks with digital transformation, as the results show that these two factors only account for about 3.73 points out of a total of 5 points.

After being interviewed, a 26-year-old automation mechanical engineer said, *"I see that work productivity has increased, and document storage and transmission are easily done."*

Leadership: In this aspect, the average score is 3.923/5 points. Therefore, organizational leaders also have a significant impact on the readiness of employees to adapt to digital transformation.

Leadership within a company has a significant impact on the readiness of workers in digital transformation. Leaders play an important role in setting strategic direction and

driving change within the company. According to interview results, most workers and experts affirm that leadership has an impact on their readiness for digital transformation.

"The senior leaders in my bank also proposed and directed our bank to be a pioneer, to try hard in digital transformation. Almost all employees responded well," A female bank employee stated her viewpoint.

They realize that leadership motivates employees by encouraging and supporting innovation activities. Employees are encouraged to learn and develop new skills and be ready to adapt to digital transformation. Another important aspect is that leaders set clear goals and determine the necessity of digital transformation, publicize and help employees understand the importance and purpose of digital transformation.

The perspective of a 25-year-old female Viettel employee on this issue is as follows :*"At my company, from senior leadership to grassroots leaders, everyone advocates the importance of digital transformation, promoting readiness for learning and adaptation to digital transformation. And employees are gradually getting used to this."*

Perceived benefits: significantly affects the readiness of employees in a business to adapt to digital transformation. This is clearly demonstrated by the high average value of 4.03. Employees have a clear understanding of the benefits that digital transformation brings, and this aspect has a major impact on their readiness to adapt to digital transformation when they realize that digital transformation helps them increase work productivity and reduce the time spent on tasks at a high level, with an average value of 4.17 out of 5. An electrical engineer who was interviewed stated, *"Digital transformation has brought and is bringing many benefits to both me and the company. And here are some of the main benefits: saving time and effort, increasing flexibility and convenience, enhancing connectivity and interaction, and strengthening the ability to work and learn remotely."*

Similarly, a 23-year-old female employee working in the banking sector stated the benefits of digital transformation in this field: *"Digital transformation helps people work smartly and quickly, helping me save time. For example, now I have many international payment sets. Instead of manually checking the files, there will be software that can check the information, results of all customer systems, and companies that have a need for money transfer. From there, they can check if the company has bad debts or which side the company has made payments to. That is one of the ways digital transformation helps in the banking industry."*

Regarding the benefits that help increase their income, the average value is low at 3.88. This is because, in addition to the benefits of increased salaries for those with knowledge and skills to adapt to digital transformation, there are also concerns about the possibility of reduced salaries for some employees who are not yet prepared to adapt. This will be more evident when analyzing the results from the perspective of risk perception.

Perceived risk: In addition to perceiving the benefits, employees also have an objective view of the risks associated with digital transformation, which significantly impacts their readiness to adapt to it, with an average score of 3.314/5. Employees are concerned about their ability to meet the high demands of digital transformation, which poses a relatively high risk of job loss, affecting their readiness to adapt and limiting risks.

Regarding this issue, an interview with a male manager expressed the viewpoint: *"Indeed, if the digital transformation process occurs synchronously and extensively, there will be challenges for those at lower levels. For example, new employees or those who are not really necessary. Digital transformation makes work more convenient and efficient, everything is automated, so the number of employees can be reduced. The risk of digitization replacing humans is significant."*

However, there is also another perspective that employees are not afraid of being replaced. In an interview, a male automation mechanical engineer said, *"The risk of job loss and being replaced is one of the reasons to worry about, but I don't think that's the main reason. I am not afraid of being replaced by digital skill applications like Chat GPT, AI. On the one hand, artificial intelligence is indeed powerful, but in my work, machines and AI cannot replace humans. I still have to be the one who makes decisions and controls the quality of the work."* The concern about reduced income has an average score of 3.24/5, indicating that employees tend to fear the risk of reduced wages, as well as finding it difficult to find other jobs if they lose their current job. These risk perceptions of employees give them a more objective and realistic view of the need to adapt to digital transformation.

Readiness: Most survey participants have a clear understanding of the level of readiness for digital transformation. According to the Likert scale, the level of readiness in this group reaches 3.99/5 points, which is a relatively high score. This shows that employees have an objective view of digital transformation, specifically its benefits, risks, and value. Based on these objective views, they may be more willing than ever to participate in the digital transformation process.

As a 22-year-old office worker said: *"... there is no field or profession that is not digitized. Even when shopping, we can see fruit and vegetable sellers integrating QR codes and electronic wallets for easy payment. They have adapted to digital transformation. So why don't I do the same...?"*

A similar view was expressed by a 26-year-old office worker regarding the readiness of all employees in the company: *"Depending on the age of the employee, I see that digital transformation is easier to adapt to and suitable for younger generations. But most people are trying to adapt, ready to apply the digital transformation to work to increase work efficiency."*

Through the interview results combined with the Likert scale, it is evident that the level of readiness of workers in digital transformation is relatively high, indicating that this is happening every day and is consistent with the development trend of the times.

5. Conclusion

The study has identified groups of readiness-related factors, such as self-efficacy, attitude, characteristics of the employee, leadership, and perceived benefits and perceived risks. According to the findings of the analysis, the leadership's support for the digital transformation process has not been felt by the employees, who lack confidence in their ability to embrace digital transformation. This implies that managers of small and medium-sized businesses must be more determined, communicate more effectively about digital

transformation, and motivate employees to participate through more specific and effective measures. This will also increase employees' confidence in the digital transformation process, making them more proactive in capturing and reaping benefits and mitigating risks associated with this transformation. When employees are prepared for digital transformation, they benefit and advance toward their personal objectives, thereby contributing to the achievement of the organization's objectives.

Future research: Further studies may consider the following directions: Quantifying the impact of the aforementioned factors on SMEs' employees' readiness for digital transformation; Consider the effect of demographic variables as moderators; Concentrate on sectors and employee groups with distinct demographic characteristics; incorporate more variables into the analysis. Focus on particular aspects, such as leadership or enhancing the competencies of employees, to motivate them to better adapt to digital transformation.

Abstract

Warehousing has been played important role in adding value in the supply chain. Currently, with rapid development of information and communications technologies (ICTs) with usage of Cyber-Physical systems, big data, warehouse management systems, sensor networks will improve productivity as well as boost up levels of customer service in warehouse operation. These smart technologies named barcode, RFID, auto guided vehicle (AGV), WMS... are useful tools that can be flexible with the whole warehouse system and increase efficiency and profitability in fulfillment operations for many orders...The research suggests that ICTs should apply depend on companies transactions for its benefits. This paper suggests that the board management in logistics companies make a good decision in investing in advanced technology.

Keywords: *ICTS, warehouse operation, RFID, WMS, Barcode, AVG*

1. Introduction

Warehouse is one of added- value parts in logistics process. The fact that it is a place where thousands of customers orders are carefully handled under the complex tasks and high responsibilities in order to meet the customer need of lead-time, on time delivery. In logistics 4.0, ITCs have enabled company to be more productive, fully operational in improving of customers service levels at the seasonable cost in term of the warehouse management. There is a comprehensive software package for warehouse management. Thanks to its communication capacities with the various systems involved in the logistics process, it enhances the features and operation of the devices, thereby ensuring the highest level of efficiency of the operation. The managers have planned their resources (human resources, material equipment handing, packaging ...) in the peak reason or for the medium term, long term for its smooth processing (René B. M. et al., 2017). There have been thousands of orders received daily, across a wide range of thousands of stock keeping units (SKU), serving all consolidated orders or separated orders and shipping in hundreds of vehicles. In the

conventional warehouse, it is highly appreciated the significance of warehouse management system (WMS) in order to save delivery- time, order entry accurately, avoid mistakes in routine practices. In this paper would like to present the usage barcode, RFID, auto guided vehicle (AGV), WMS....in warehouse operation to achieve its customers' requirements.

Hence, this paper is aimed at answering the following research questions:

1. Overview literature of ICTs especially usage barcode, RFID, auto guided vehicle (AGV), WMS....in warehouse operation.
2. What are values of ICTs once they have been applied in warehouse?
3. Which proposal should be made about ICTs widely used in warehouse to keep up with high technology development trend of smart warehouse?

2. Literature review

Most of products handled at those of types of warehouse (manufacturers, distributions centers, B2C- orders) where orders received and shipped must be on time delivered, right quantity, right place, right condition. In order to effectively manage physical distribution process from manufacturers, shopping malls to end users, the managers of warehouse tasks have to monitor properly the tracking of orders. Therefore, Warehouse Management Systems (WMS) is an effective solution to increase customers service. It has played an important key to save human resources by tracking customers' orders (advance shipment, time shipment, order quantity, feedback, shortage orders managements...). WMS is considered as an effective tool for supporting warehouse 's customer service level in terms of inventory control (Andiyappillai. N. (2020). WMS can help warehouse managers to keep an intensive check of flow of inbound of goods and outbound goods. In order to keep in touch with each SKU (stock keeping unit) that has different size, style, color, location (Silver et al., 1998). WSM applied on warehouse operations as a tool to describe all existing interaction between the parts composing the warehouse processes in order to standardize and optimize material flows (customer services, storage location control, picking lists). WMS is designed all distinct features for eliminating of entering wrong data. Its functions to gather information available for those who have right to get access to get information for solution. Warehouse leaders can report all activities (how the goods are shipped; what are goods picked). It connects Sales offices, Customer service, Transporter to process orders shipment. Barcode encodes product information into bars and distinct characters, making it much convenient in handling, tracking goods stored in warehouse. Barcodes or RFIDs are often used in WMS for products tracking, RFID can improve the efficiency of the warehouse management and make a rapid self-recording of receiving and delivery Žunić at al., 2018). In logistics 4.0, robots or self -driving vehicles named AVGs are increasingly popular in warehouse. They have played an important role in replacing humans working in process. According to Hana Neradilova (2017) AVGs have developed into a reliable and efficient technological equipment during more than fifty year. AGVs is also a practical idea to reduce the inefficient routine practices to avoid inaccuracies as least as possible as well as to solve the labor shortage issue (Navodika et al., 2019). For

the past ten years, AGVs have been widely used in automated material handling in industrial environments (De Ryck et al., 2020). AGVs have been used nowadays in factories to make factory environments more intelligent where the products themselves will be used to determine their next required process (Mehamit et al., 2018). In warehouse tasks, AGVs are automatically controlled vehicles that are used in-house for floor bound conveying (Markis et al., 2019).

The role of ICTs in warehouse operation

It is undoubted that more and more ICTs are used in the warehouse operation. This usage will dramatically impact on how the warehouse will be organized in relation to new technologies and configuration. ICTs will coordinate intralogistics flows and different hardware systems, integrates manual and automatic operations. The benefits of using ICTs in term of delivering palletized goods in warehouse are:

- Saving the labor cost and operation expenses:

Warehouse manager's responsibilities are to care their employees, health and safety, working hours. (Alan 2010). The ICTs such as AVGs are considered like robots working in warehouse without any requirement benefits as well as remuneration or social welfare. We do not worry about the headcount's resources rising annually or thinking of yearly upgrade salary or other benefit of forklift drivers, day-off for holidays, or national days or motivation base on KPI performances.

- Putting safety priority:

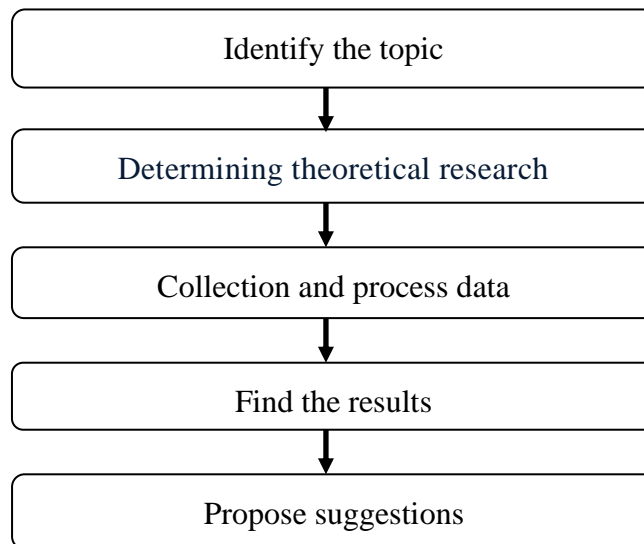

Well-designed ICTs determine the most effective allocation of both labor and space in order to reduce waste. These AVGs let you place pallets, shelves and other equipment's that need to accommodate for in warehouse, optimize the flow to movement. By contrast, equipment run by human operators, such as forklifts, do not have as many built-in safety mechanisms and ultimately rely on human input, whereas a human operator always has the potential to become distracted or fatigued and therefore cause an accident. (Tezer & Aynas (2018)

- Improving warehouse productivity and increasing accuracy:

In warehouse operation, there are thousands of tasks happening daily with thousand order waiting for handling. In peak reason, mistakes may be arisen by people without controlling or anticipating any trouble. By replacing the human resources with AVG, a lot of potential inaccurate workflows or workload will reduce partially and increase output, this helps operation become more smoothly and productive. (Barreto et al., (2017). With SKU, barcode technology, they enable of inventory tracking, management, location of goods, improving inventory turnover ratio and low deadstock quantities.

2. Method

The research was held from February to May 2023 which qualitative approach is used with the techniques of synthesis, comparison, and data descriptive statistics collected by short interviews with managers in logistics companies. There are some steps as below:

The information is collected from primary and secondary sources. The first sources are interviewed with managers in warehouses of logistics companies located in Ho Chi Minh, Dong Nai, Vung Tau, Long An and Binh Duong Province. The author has conducted a survey of 140 companies with different logistics service supply. Data is processed through Excel dashboard software.

Secondary sources are collected from researches published in confirmed journals, e-books.

3. Results

ICTs are applied directly to business in logistics service providers more and more deeply and widely, considered as a great tool for competitions between companies. According to Vietnam Report (2022), 100% of logistics enterprises have invested in digital transformation, of which 86% think that applying ICTs will have many benefits such as more work volume in a while, improved efficiency, etc. increase sales ; 36% think that ICTs in logistics activities will help customers approach to international markets, gain experiences when trading in international environment. In fact, logistics enterprises apply common technology platforms in their entire operations, emerging technology platforms are deeply paid much attention to. Of which, about 68% of logistics enterprises have applied revolutionary 4.0 advances to their operations such as IoT (19.4%), cloud computing (18.4%), artificial intelligence (18.4%), big data and blockchain (14.3%).

In the paper, the author conducted a survey of 140 logistics companies. Among them, 20% surveyed companies in the field of providing international 3PL/4PL services, followed by the field of domestic forwarding and transportation, warehousing services. Generally, of the software that logistics enterprises are applying, the number of barcode, RFID, auto guided vehicle (AGV), WMS are applied by enterprises the most (over enterprises participated in the survey). And the results are statistically calculated by the author through Figures 1, 2.

Most of warehouses located in Ho Chi Minh city where is the largest economic center and most populous city. It also processed most of on-line orders, B2C -processing orders.

Barcode technologies and WMS software are used in most of warehouse operations, with a percentage of 36 % and 29 % respectively.

AVG technology applied at least with the rate of 14% of 140 warehouses collected.

Figure 1. Location of warehouse of logistics companies

Figure 2. ICTs are used in warehouses

4. Discussion and Conclusion

Most of advantages can be listed that 28 percentage of answers showed that productivity improve. (connect to customer service to control accuracy inventory management)

Some disqualified workers are reduced with 20 percentage of surveyed companies. When ICTs applied for warehouse operation, some part of shop floor job such as checker, forklift drivers, pickers, packers will be reduced. Otherwise, qualified jobs such as technical trainers, maintenance workers will replace the labor force.

As most of companies' answers said that there is high initial investment and Wi-Fi infrastructure linkage for the whole systems with 34 % and 27 % of replies respectively. In normal situations, in order to make sure throughout operation smoothly, the managers have to plan the number of headcounts really in need in operations such as forklift drivers, forklift trucks, pickers, customers service as well as budget for that labor forces. On the other hand, the expense invested in infrastructure of the warehouse environment are enormous. For example, with the same volume of through-put, factory requires planned more than AGVs to handle all the quantity of pallets. There is imbalance in financial status when inventing AGVs replacing shop floor workers. The money company needs to pay per month to cover all operations shall increases more than 50 % of cost. According to some researchers found that the vehicle guidance is realized by some hardware like wires or lines that are placed in the working environment of the robot (Markis et al., (2019). The conventionally used AGVs require also a well-defined, structured and obstacle-free working environments according to Mohammed et al., (2019) and De Ryck et al., (2020). Moreover, an infrastructure wireless network is the wireless network that contains a wireless router/access point and enables other computers to connect to it wireless. The disadvantage of infrastructure mode wireless networks is the additional cost of access point hardware. The company needs to invest in complete synchronization of the warehouse IT system.

Training cost for skills and expertise

Patrico & Mendes (2020) believed that new skills and expertise are required to implement and maintain the systems and hence existing or potential employees must be retrained to new processes, sometimes to a higher technical aptitude. Moreover, the labor market has not yet met the labor requirements of high professional and technical skills of enterprises and organizations, including FDI enterprises. Industrial parks, export processing zones, high-tech zones, FDI sector and labor export still face difficulties in recruiting highly qualified and technical workers to meet the transfer of new science and technology from foreign. Vietnamese workers are still weak in foreign languages and lack understanding of the law and culture of the country they come to work for.

From the above analysis, this study proposes some suggestions for applying ICTs to warehouse operation.

Firstly, it is essential for board management to raise awareness of efficiency of ICTs. They may build business cases in long terms. They need to see the benefit of ICTs and operation costs so that they allow smart technology to be integral part in every warehouse operation.

Secondly, it is agreed that implication of new technology in warehouse operation also brings challenges to workforces, to the management boards. Therefore, they consider to built human strategies for flexible change and adaptability with high customers services.

To sum up the application the new technology will bring lot of advantages as well as disadvantages. At the moment, it is possible to confirm that using ICTs is one of the best solutions in warehouse operation in terms of productivity and its low qualified jobs.

CASHLESS PAYMENTS IN VIETNAM: BEFORE AND DURING THE COVID-19 PANDEMIC

Dr. Nguyen Thi Vu Khuyen

khuyen.nguyenthivu@hust.edu.vn

School of Economics and Management,

Hanoi University of Science and Technology, Vietnam

Abstract

The article studies the impact of the COVID pandemic on the situation of non-cash payment activities in Vietnam. By collecting data on domestic payment through payment methods, quantity, and balance of demand deposit accounts in Vietnam for the two periods which are before and during COVID, the author analyzed vividly and detailly the growth of non-cash payments in general and through payment methods in particular in case of without and with COVID. As a result, cashless payments started to show growth before COVID appeared, but COVID is undeniably a strong push to make this payment business grow stronger and more impressive, especially for payment methods via payment orders, internet banking, and mobile banking.

Keywords: *Cashless Payments, the impact of the COVID pandemic, Vietnam*

1. Introduction

Cashless payment is the trend of global economic and civilized development. However, depending on the level of economic growth, technology, people's knowledge and consumer culture, each country will have a different roadmap to non-cash payment. In recent times, especially under the impact of the Covid 19 pandemic, Vietnam has been catching up very quickly with this trend. Non-cash payment activities tend to increase over the years, both in terms of transaction value and volume. According to statistics of the State Bank of Vietnam, non-cash payments in 2022 have doubled compared to the previous year. The use of cashless payment instruments is driven by ease of use in micropayments and retail, scheduling financial transactions that can be managed anywhere, reduce transaction costs and be more efficient than using cash payment instruments (Irvi Givelyn et al., 2020). These benefits seem to have been recognized by the Vietnamese public from students, officers to small retailers in traditional markets in big cities and towns. When people get used to this form of payment, it will create momentum for even stronger growth in the future.

2. Literature review

Cashless transaction refers to an economic context in which goods and services are traded without the use of cash, either through electronic transfers or by check payments (Hock-Han Tee and Hway-Boon Bee, 2016). In addition to electronic transfers and checks, payments through electronic wallets and smart banking applications have become familiar and dominant today. Therefore, it is possible to expand the concept of non-cash payment as a form of payment using electronic payment means applying digital technology such as: E-

wallet, MobileBanking, InternetBanking... or indirect payment. through credit institutions instead of buyers and sellers directly exchanging with each other as is the practice today (Nguyen Dai Lai, 2020).

Non-cash payment methods:

- Checks: Checks are one of the oldest cashless payment methods. In this method, the person issues a check for a specific amount to another person. Checks are deposited in the respective bank. The bank processes a payment through a clearinghouse. All transactions are done through recorded checks and proof of payment.

- Bill of exchange accepted by the bank: a certificate confirming the deferred payment in international trade.

- Automated Teller Machines (ATMs): are machines that withdraw money, deposit money, transfer funds between two or more accounts, and pay bills. Automated teller machines will be used more often to make many online payments such as utility bills, airline tickets, purchases, etc.

- National Electronic Funds Transfer (NEFT): This is an online platform where banks exchange value, thereby enabling instant transfers between banks to one or more beneficiaries for each individual. core.

- Real Time Gross Settlement (RTGS): This is an online payment system used by banks and financial institutions to transfer money directly and instantly from the bank account of one party to the bank account of another party, with the transferred amount being the full amount (gross) without any deductions or charges. The RTGS system operates 24/7 and is operated by the central bank or financial institution to ensure safety and reliability in the payment process. Using RTGS reduces payment risks and speeds up the payment process, while providing detailed information about financial transactions that users can use to verify their transaction history.

- Mobile Banking: this is a service provided by a bank, allowing users to use the bank's online services, perform online transactions through an application on the device. mobile.

- Electronic transfers (E-transfers): Electronic transfers are made over the internet on PCs, laptops and other devices. Bank customers who have signed up for online banking can perform basic banking transactions via the web.

- POS terminals: POS is deployed to point of sale locations where users swipe their electronic cards through them to pay for purchases or services instead of using raw cash. Since the POS terminals are online in real time, the customer's bank account is instantly debited for the value of the purchase made or the service enjoyed.

- E-wallet: An electronic wallet that stores card numbers and cash. This is a virtual wallet that can store credit cards, debit cards and other information. Both the customer and the merchant of the e-wallet require a smartphone with an active internet connection.

- Credit card: This is a plastic card used to pay for goods or items delivered on a consumption-first, pay-later basis. Each time the customer makes a payment, the customer is granted a credit by the card issuer and will be charged interest after a certain period of time according to the bank's regulations.

- Debit Card: This is a new form of value transfer in which the cardholder, after entering a PIN, uses a terminal and network to enable the transfer of value from their account to the merchant's account.

- Cash card: is an instant payment card without a pin code at public card acceptance points, often integrated with public transport cards, student cards, employee cards, etc.

- QR code payment is the most modern method of payment & receipt of payment today, allowing customers to use the built-in QR-Pay feature in Mobile Banking applications of domestic banks and e-wallets. on mobile phones to pay for orders.

Cashless payments bring many benefits to consumers, businesses, and society.

Firstly, cashless payments save consumers and businesses time, as they don't have to spend time counting money, changing money, or queuing for cash delivery.

Secondly, with cashless payments, users don't have to worry about losing money, or having their credit cards and personal information stolen. Current electronic payment facilities are secure and well encrypted.

Thirdly, cashless payments make it easy for consumers to track their spending and manage their personal finances. Businesses can also easily manage their finances and reduce the risk of loss due to cash.

Fourthly, cashless payments reduce costs for printing, transporting and storing cash, as well as for collection, counting and financial control.

Fifthly, cashless payments offer flexibility to consumers and businesses in using different means of payment such as credit cards, wire transfers, e-wallets, internet payments, and many other forms of payment. Thereby bringing convenience and boosting spending.

Sixthly, cashless payments reduce financial crimes such as counterfeiting, counterfeiting, and stolen cash. More importantly, the government will limit tax evasion and corruption.

Finally, cashless payments reduce the use of banknotes and coins, helping to reduce waste and protect the environment.

3. Results

3.1. Research time and data

The COVID epidemic began to spread in December 2019 in Wuhan city, Hubei province, China and then quickly spread around the world. In Vietnam, from January 2020, the government has implemented epidemic prevention and control measures including border control, closing entry points and issuing guidelines on how to prevent and control the epidemic. On January 23, 2020, Vietnam recorded its first case of COVID and then the number of infections increased rapidly. However, the Vietnamese government quickly put in place measures to control and prevent the disease from spreading. These measures include monitoring, control and isolation of suspected or positive COVID cases; mandatory mask wearing in public places and on transport; Social distancing and limited gatherings. By the beginning of 2022, the epidemic began to break out strongly and peaked in mid-March 2022. By the end of the second quarter of 2022, the epidemic was basically under control.

Thus, it is possible to mark the milestones of starting the epidemic in the first quarter of 2020, ending in 2022.

So, the study time is also divided as follows:

- Before the pandemic: Q1 2018 to Q4 2019
- In the pandemic: the first quarter of 2020 to the end of 2022

Data on payment is collected and aggregated by the author on the website of the State Bank of Vietnam. Data is published quarterly.

3.2. Current status of cashless payments in Vietnam before and during Covid

3.2.1. Current status of payment deposit accounts

To make non-cash payments, people need to have payment deposit accounts at commercial banks. The characteristics and buying habits of Vietnamese people are concentrated in concentrated and spontaneous markets, so in the past, small traders only received cash. They do not have a POS tool, nor do phone payment methods that are not yet popular and convenient. However, with the sales promotion of commercial banks, the number of accounts and payment deposit balances has increased significantly. The fourth quarter of 2019 had a total number of accounts of 88.5 million accounts, an increase of 11% over the same period in 2018. In terms of balance, the end of 2019 represented a remarkable increase compared to the same period in 2018 with an increase of 32%. This shows that consumption habits and payment through bank accounts have increased, which should motivate people to keep more money in their accounts.

When the epidemic began to increase, due to blockade measures, restrictions on mass gatherings and concerns about hygiene when using paper money to pay, many small businesses and people all over the country opened more accounts. account and maintain more payment deposit balance. In the fourth quarter of 2020, the number of accounts is more than 100 million and the balance is 666.7 billion VND, up 13% and 33% respectively over the same period in 2019. The fourth quarter of 2021 marks a strong increase with 21% in volume and 41% in current account balance compared to the same period in 2020. The deposit account balance was maintained at a record level of 1,051,018 billion dong by the end of the first quarter of 2022, as well. This is when the number of people infected with Covid also reached its peak. It is clear that the Covid epidemic has a strong impact on people's payment habits. From being forced to use payment by wire transfer, scanning QR codes, cards, etc., now people have formed a habit and realize the convenience and enjoy the added benefits of payment methods. new. By the third quarter of 2022, the number of accounts was 141.2 million and the balance was maintained at VND 986 trillion, up 88% and 163% respectively over the same period in 2018.

3.2.2. Status of domestic transactions via payment methods

- Before covid:

Total domestic payments through cashless payment methods increased significantly in 2019 at a fairly significant rate of 57% and 27% respectively in terms of transaction

volume and value. Thus, even before the Covid-19 epidemic, Vietnam had a growth in both quantity and quality in non-cash payment activities.

Table 1. Domestic payment via payment methods in the period of 2018 -2019

	2018				2019			
	Quantity (transaction)	%	Value (Billion VND)	%	Quantity (transaction)	%	Value (Billion VND)	%
Bank card	229,220,567	20.9	592.205	0.6	326.727,521	19.0	798,870	0.6

Structurally, the old payment methods such as checks, payment by collection and other methods (bills, domestic letters of credit, money orders, etc) have also shown a clearly loss of position and gradually replaced by payment via electronic payment order.

Figure 1. Structure of domestic payment transactions by payment methods 2018-2019

Source: author's own synthesis and calculation

- During and after Covid:

The trend of increasing cashless domestic payments continues to increase at an impressive rate, especially after the Covid-19 raging. In 2020, the total number of transactions through payment methods increased by 72% compared to 2019. However, the growth rate of transaction value is quite modest at 16%. The reason is due to the increase in small value transactions, demonstrating the participation of individual consumers in payment as well as changes in people's payment habits.

In 2021, the growth rate of the number of transactions will slow down, partly because 2021 is the year the epidemic is at its peak. Almost all economic and commercial activities

are significantly affected. However, in 2021, Vietnam's stock market boomed again because the country has demonstrated good disease control capabilities and had appropriate recovery and disease prevention strategies. The development of financial technology makes it possible for retail investors at home to still buy and sell securities through non-cash payment. Therefore, although the growth rate in the number of transactions was only 36% (half of the previous year), the transaction value still increased by 16% (equal to the previous year).

The year 2022 marks an amazing growth of total number and value of cashless payments with 89% and 32% respectively. In early 2022, although the number of people infected with Covid reached its peak, the vast majority of people had been vaccinated, so symptoms were mild and no longer a cause for concern. People are also ready for herd immunity. The state completely lifted the blockade and other negative measures on the economy. By this time, the habit of paying via banks and e-wallets has been formed. Many people clearly see the benefits and continue to pay cashless in their daily small purchases.

Table 2. Domestic payment via payment methods in the period 2020-2022

	2020		2021		2022

Source: author's own synthesis and calculation

Figure 2. Structure of domestic payment transactions through payment methods 2020 - 2022

Source: author's own synthesis and calculation

Payment method via electronic payment order continues to dominate in non-cash payment. By 2022, the proportion of payment transactions via payment orders has reached 90%. While checks, collection and other methods are almost no longer used and will disappear in the not too distant future.

Here we will go deeper into the payment situation of each method.

- Data of domestic payment transactions via bank cards

Data on domestic payment via bank card reflects the number and value of domestic payment transactions made by card reported by the issuing bank, excluding: (i) payment transactions international transactions of cards issued by overseas banks; (ii) deposits, withdrawals or transfers where the sender and receiver are one; and (iii) payments between credit institutions and customers (such as loans, repayment of loan principal/interest, or fees,...).

In 2018, each quarter the number and value of transactions via cards fluctuated insignificantly, totaling 229.2 million items and reaching a value of 592.2 trillion VND. Through 2019, the total number of transactions and the value of domestic transactions via cards increased by 43% and 35% respectively compared to 2018. Every quarter there was an increase in both the number and value of payments. In the fourth quarter of 2019, the number of domestic transactions via card increased by 57% compared to the same period in 2018. Transaction value also increased by 48% after only 1 year. Thus, the trend of using bank cards for domestic payment transactions has increased strongly even though Covid has not appeared at this time.

By 2020, domestic payment transactions via bank cards will still increase, but the rate will decrease compared to before Covid. Specifically, in 2020 the number and value of transactions increase by 40% and 24% compared to 2019. In 2021, it will only increase by 10% and 7%. This is understandable because during the epidemic, people are restricted from going out, so they do not directly use cards to pay. Instead there are more effective methods of payment such as scanning QR codes, or wire transfers. After 2021, especially after the community immunity, people have completely entered the new normal period and domestic payments via bank cards will increase again with an increase of 39% in 2022 compared to 2021. for quantity and 40% for transaction value.

- Data of domestic payment transactions via check

It can be clearly seen that the form of payment by check has decreased sharply and significantly due to the introduction of faster and more convenient payment methods and replacing traditional checks. In 2019, the number and value of domestic payment transactions via check dropped sharply by 57% and 47%. Contrast with the increasing speed of payment via bank card.

When the Covid epidemic broke out, the decline was even stronger. Compared to 2019, 2020 marked a dramatical decrease of 79% and 68% in the number and value of transactions. Transactions will continue to decline in 2021 and 2022. But at a slower rate. This also signals that in the future the method of payment by check will disappear, replaced by more modern and smarter cashless methods.

- Data of domestic payment transactions via payment orders

In contrast to check transactions, the growth rate of payment orders increased at an amazing rate. Payment order or payment authorization means a payment order of an account holder made according to a pre-printed form of the Bank or State Treasury to request the Bank or State Treasury to serve them (where the deposit account is opened) to deduct the his

account to pay the beneficiary. Account holders can place money orders through e-banking applications on mobile phones or computers easily. The increasingly developed 24/7 domestic electronic payment system has facilitated payment via payment orders to increase sharply over time. From the number of transactions of only 767 million items in 2018, after only 1 year, this number has reached 1.33 billion items, a dramatical increase of 74%. Transaction value also increased by 32%.

After the outbreak of the pandemic, the growth rate of payment transactions via payment orders continued to increase sharply. Regarding the number of transactions, the growth rate is 80% in 2020, 43% in 2021 and extremely impressive 99% in 2022. Transaction value increases at a more modest rate with 18%, 16%. and 39% over the respective years. The payment via payment orders has increased sharply in number of items but not in value, possibly because people use the application to pay for small expenses, even to buy food and daily consumer goods. The habit of going to the market to buy and sell with cash has been forced to change due to the epidemic.

- Data on domestic payment transactions via collection

The domestic payment via collection method is mainly used by enterprises in commercial activities. Over time, this method also loses its position because of the complicated application requirements, long processing time, as well as expensive bank fees. From the number of transactions of 47.6 million items with a value of 5.5 million billion VND in 2018, the numbers have decreased to only 3.5 million items and 1.5 million billion VND in 2022. However, it is quite interesting that during the complicated epidemic period, the rate of decline is not too strong, even slightly increased in 2021. During the epidemic period because of contact restrictions and your credit level. Customers are quite difficult to identify, so businesses will choose to go through a bank to collect money for goods to increase security. In 2022, after the epidemic was under control, this payment method dropped sharply by 68% in quantity and 77% in value compared to 2021.

3.2.3. Status of payment via ATM and POS

- Payment via ATM

Domestic payment via ATM in the period from 2018 to 2022 has almost no significant changes. The number and value of annual transactions are quite even, ranging from approximately 900 million to 1 billion items, and 2.5 to 3 million billion Dong, with no obvious impact of the epidemic.

Table 3. Data of ATM payments in the period of 2018 - 2022

	Quantity (transaction)	Value (billion VND)
2018	879,008,013	2,465,008
2019	1,002,928,660	2,787.556
2020	1,027,745,089	2,799,931
2021	949,272,561	2,721.062
2022	1,070,570,265	3,077,310

Source: State Bank of Vietnam

- Payment via POS

Domestic payment via POS tends to increase over time. 2019 marked a turning point in this payment method with an increase of 49% in volume and 35% in transaction value compared to 2018. However, when the epidemic broke out, people limited shopping at stores, as well as commercial centers, payment via POS has increased, but at a much lower speed. Specifically, in 2020, the number and value of transactions increased only 17% and 2% respectively compared to 2019. The numbers are 13% and 14% respectively when comparing the figures in 2021 with 2020. If the disease is under control, the growth rate will reach 52% and 47% in terms of transaction volume and value. Thus, unlike ATM, domestic payment transactions via POS are significantly affected by the Covid epidemic.

Table 4. POS payment figures in the period of 2018 - 2022

	Quantity (transaction)	Value (billion VND)
2018	208,195,398	447,058
2019	310,354.640	604,650
2020	362,222,382	619,189
2021	410,557,381	704.513
2022	623,214,527	1,032,498

Source: State Bank of Vietnam

3.2.4. Status of payment via internet banking and mobile banking

Payment via internet banking and mobile banking have many similarities leading to confusion between these two forms. It can be said that these two methods both need the condition that the devices must be connected to the internet. However, there are some differences as follows. Firstly, for mobile banking, customers can only use it on smart devices that can install applications. And internet banking can be used on any device such as mobile, laptop, ipad, connected to the internet, and customers will access the bank's internet banking website. Second, with mobile banking, customers need to enter their phone number and password to log in. As for internet banking, customers log in with the account code, the password provided by the bank and the confirmation code. Third, the transaction fee for internet banking is usually lower than for mobile banking.

In fact, both types of transaction methods will really explode in 2021. From 2021, the State Bank of Vietnam will also have complete and specific statistics on the number and value of transactions. If in the first quarter of 2020, the number of new internet banking transactions is 94.8 thousand items, in the same period of 2021 this number is 156.2 million items and in the same period of 2022 it is 243.5 million items. Thus, 2021 marks the explosive development of this payment method with an incredible growth rate of 164629%. This is an astonishing number. This is also a very serious epidemic period. For the whole year of 2021, the number of transactions via internet banking is 707 million items, and by 2022 the number has doubled to 1,404.4 million items. Transaction value also increased by 87%.

The above scenario also happens almost exactly with payments via mobile banking, even with a stronger growth rate. In 2022, the number and value of domestic payment

transactions via mobile banking increased by 139% and 107% compared to 2021. The number of payments via mobile banking is also many times higher than that of internet banking, but the payment value Mobile banking is lower than internet banking. This can be explained by the fact that the users of mobile banking are mainly retail and individual customers, with a large number of transactions but small amounts. While internet banking is usually used by institutional customers and businesses.

Table 5. Payment data via internet banking

4. Discussion and Conclusion

It can be said that cashless payment has really developed very quickly in both quality and quantity from 2019 onwards. 2019 is a year when the economy has made important qualitative progress in the context of the world economy's decline and complicated developments. Especially, the market service industry has a high growth rate of 8.41%, which is the main driving force contributing to the economic growth of our country. Thereby creating a premise for remarkable development in the future. Modern non-cash payment methods gradually replace traditional payment methods. Payments via payment orders, via the internet and mobile banking gradually dominate due to the development of banking technology and the trend of the times. For a country that is used to cash payments and reserves, a strong push is needed to gradually transition to cashless payments. The development of banking technology is an important factor, but perhaps it is the Covid epidemic that is a significant push to change the habits of consumers and businesses.

However, despite the rapid and strong development in the past 5 years, non-cash payment has not been able to cover the whole country and completely replace cash. The reasons for this can be summarized as follow:

Firstly, the popularity is not high. Although cashless payment is becoming a trend, however, the adoption and use of this means is still not fully popular in Vietnam, especially in rural areas where the internet and payment devices as well as people's understanding is still limited.

Second, the dissemination of knowledge and information to the entire population is not complete and synchronous. Some users still lack information and experience in using non-cash payment methods, which leads to difficulties in the process of using and becomes a barrier in popularizing the use of this means.

Third, Cybersecurity risks make many users afraid to expand the use of cashless payment methods. Cashless payments can create cybersecurity risks such as loss of personal information, hacked accounts, or cyberattacks against payment service providers.

- Some recommendations to increase the popularity of cashless payments:

Firstly, building infrastructure: Organizations need to invest in infrastructure to support cashless payments, including the development of electronic payment systems, network infrastructure, card readers, electronic terminals.

Secondly, promote cashless payment solutions: Organizations need to promote cashless payment solutions such as e-wallets, credit cards, online transfers, payments via mobile apps motion. Organizations can create promotions to attract users to use these payment methods.

Thirdly, Education and advice: Organizations need to educate and advise users about cashless payment methods, the benefits and safety of using them. Policies that encourage the use of cashless payments also need to be clearly communicated for users to understand and apply.

Fourthly, create trust and safety: Organizations need to ensure that cashless payment methods are secure and safe. Additionally, organizations should have policies in place to support customers in the event of problems or errors using these payment methods.

Fifthly, Support for businesses: Organizations need support for businesses to transition to cashless payments, including providing equipment, staff training and guidance, technical support, etc.

CREDIT RISK MANAGEMENT ENABLING BY MACHINE LEARNING

Truong Thi Hoai Linh

linhth@neu.edu.vn

School of Banking and Finance, National Economics University, Hanoi, Vietnam

Abstract

Application of Machine Learning (ML), a branch of Artificial Intelligence (AI) in banking, particularly credit risk management, has been a most discussed topic for some time. A growing number of organizations and institutions are exploring different variants of how the technology can be effectively applied. This has happened because ML has been proven to genuinely add value across the entire credit value chain. This article contains two main ideas: (i) systematization of Machine Learning and (ii) literature review the advantages of Machine Learning algorithms in banks' credit risk management.

Keywords: *Machine Learning, risk management, credit risk.*

1. Introduction

Machine Learning advances heavily affected a wide variety of industries in the past decades, ultimately transforming people's daily life. Artificial Intelligence has been applied to almost every human activity, including pattern recognition, image classification, business, agriculture, transportation, and finance. This paper focuses on ML applied to finance and banking sectors. Modern financial systems rely on credit and trust. Credit risk is a fundamental parameter that measures and predicts the default probabilities of a debtor. The correct estimation of credit risk is paramount for the entire system. Failing in the credit risk estimation can lead to systemic failures. Consequently, lenders devote large amounts of resources to predict the credit worthiness of consumers and companies to develop appropriate lending strategies that minimize their risks. Historically, credit risk approaches use statistical methods such as Linear Discriminant Analysis and Logistic regression. These methods, however, do not easily handle large datasets.

Advances in computing power and availability of large credit datasets paved the way to AI-Driven credit risk estimation algorithms such as traditional ML and Deep Learning. Conventional ML techniques (e.g. k-Nearest Neighbor, Random Forest and Support Vector Machines, etc.) are more effective and flexible than statistical methods. In particular, the vital branch of ML techniques applied to large credit risk data lake outperform their predecessors both in accuracy and efficiency. This paper presents a systemic review of the advantages of ML algorithms in banks' credit risk management.

2. Conceptual Framework

Definition

When it comes to Machine Learning (ML), we must first mention **Artificial Intelligence (AI)**. McCarthy (1998) described AI as computer behavior of simulating humans and eventually solving problems as humans do. Machines have typical human intelligence such as knowing how to think, how to solve problems, and how to communicate due to understanding language and speech, learning and adapting on their own. The advent of AI led to the development of the concept of Machine Learning and Deep Learning (DL). AI is the largest circle, followed by the Machine Learning circle and finally the smallest circle in Deep Learning. Machine learning is a branch of AI and computer science which focuses on the use of data and algorithms to imitate the way that humans learn, gradually improving its accuracy. In particular, Deep Learning is an ML technique involving neural networks (neural networks) that allows machines to train themselves. DL is driving the strong development of AI in many fields today. This article focused on ML.

Figure 1. AI, Machine Learning, and Deep Learning

Source: Goodfellow et al. (2016)

ML is a combination of computer science, engineering, and statistics. It has been highlighted as a tool that can be applied to various problems, especially in areas that require data to be interpreted and informed (Awad and Khanna 2015). ML is capable of detecting meaningful patterns in data and has become a universal tool for almost any task faced with the requirement to extract meaningful patterns from datasets. When faced with the requirement to extract meaningful samples from data with the vast complexity of the samples to be studied, a programmer may not be able to provide a clear and detailed description of the implementation process. ML addresses this challenge by providing programs with the ability to "learn and adapt." ML programs learn and improve and can be applied when the problem to be handled has the dual challenge of complexity and the need for adaptability (Shalev-Shwartz and Ben-David 2014). Simply put, the standout feature when it comes to ML is the ability to "self-learn", meaning that over time, space, with more data, algorithms allow the system to calculate more "intelligently", thereby "narrowing" errors and giving more accurate results. For the sake of simplicity, the more it operates, the more "self-learning" the ML application system becomes, the smarter it is, and the less dependent it is on human intervention.

General application

ML has a wide range of applications in science and manufacture, especially those that need to analyze big data. Some popular applications as follows:

- Natural Language Processing: word processing, human-machine communication...
- Pattern Recognition: speech recognition, handwriting, fingerprint, computer vision ...
- Search (Search Engine).
- Medical diagnostics: X-ray image analysis, automatic diagnostic expert systems.
- Bioinformatics: classification of gene sequences, the process of forming genes/proteins.
- Physics: astronomical image analysis, interparticle impact...
- Financial fraud detection: credit card fraud.
- Stock market analysis.
- Game play: automatic chess play, action of virtual characters.
- Robots: is a synthesis of many sciences, in which Machine Learning creates the nervous system/brain of robots.

Categories

Supervised Learning: Suppose you are trying to learn a new concept in maths and after solving a problem, you may refer to the solutions to see if you were right or not. Once you are confident in your ability to solve a particular type of problem, you will stop referring to the answers and solve the questions put before you by yourself. In Supervised Learning, the model learns by example. Along with our input variable, we also give our model the corresponding correct labels. While training, the model gets to look at which label corresponds to our data and hence can find patterns between our data and those labels. Supervised Learning is divided into Classification and Regression.

Unsupervised Learning: This approach is applied to examine data's inherent structure and derive insightful information from it. This technique looks for insights that can produce better results by looking for patterns and insights in unlabeled data. There are two types of unsupervised learning such as Clustering and Dimensionality reduction.

Semi-supervised Learning: Semi-supervised learning lies on the spectrum between unsupervised and supervised learning. It combines the most significant aspects of both worlds to provide a unique set of algorithms.

Reinforcement Learning: The goal of reinforcement learning is to create autonomous, self-improving algorithms. The algorithm's goal is to improve itself through a continual cycle of trials and errors based on the interactions and combinations between the incoming and labeled data.

Popular algorithms

The regression algorithm involves modeling the relationship between variables. The most common regression algorithms in Machine Learning are: Ordinary Least Squares Regression (OLSR), Linear Regression, Logistic Regression, Stepwise Regression, Multivariate Adaptive Regression Splines (MARS), Locally Estimated Scatterplot Smoothing (LOESS) ...

Instance-based including k-Nearest Neighbor (kNN), Learning Vector Quantization (LVQ), Self-Organizing Map (SOM), Locally Weighted Learning (LWL)...

Regularization including Ridge Regression, Least Absolute Shrinkage and Selection Operator (LASSO), Elastic Net, Least-Angle Regression (LARS)...

SVM (Support Vector Machine) algorithm: SVM is an algorithm belonging to the Supervised Learning group (Supervised Learning) that is very commonly used in classification or regression problems. SVM is based on the statistical learning theory formulated by Vapnik and Chervonenkis (1995). The idea of SVM is to find a hyper plane that can separate the data sets to be classified so that the margin from the superplane to the sets to be classified is equivalent and largest.

Decision Tree algorithm: A decision tree is a model that belongs to the group of Supervised Learning algorithms. A decision tree is a structured hierarchical tree used to classify objects based on a series of rules. When giving data about objects with properties along with their classes, the decision tree generates rules to predict classes of unknown objects. This algorithm includes Classification and Regression Tree (CART), Iterative Dichotomiser 3 (ID3), 5 and C5.0 (different versions of a powerful approach), Chi-squared Automatic Interaction Detection (CHAID), Decision Stump, M5, Conditional Decision Trees...

Bayesian including Naive Bayes, Gaussian Naive Bayes, Multinomial Naive Bayes, Averaged One-Dependence Estimators (AODE), Bayesian Belief Network (BBN), Bayesian Network (BN)...

Clustering algorithms, like regression, describe the problem class and the method class. Clustering methods are organized according to modeling methods such as centroid-based and hierarchical. All methods involve the use of structures inherent in the data. It is a need to best organize data into maximally popular groups. Including k-Means, k-Medians, Expectation Maximisation (EM), Hierarchical Clustering...

The combined rule-learning algorithm extracts the rule, which best explains the relationships between variables in the data. These rules can discover important and useful combinations in large multidimensional datasets. That can be exploited by an organization. Popular associative rule learning algorithms include Apriori algorithm, Eclat's algorithm.

Artificial neural network algorithms are models that are inspired by the structure of biological neural networks. The most popular artificial neural network algorithms are Perceptron, Back-Propagation, Hopfield Network, Radial Basis Function Network (RBFN) ...

The Deep Learning algorithm is a modern update to Artificial Neural Networks. The most popular Deep Learning algorithms are: Deep Boltzmann Machine (DBM), Deep Belief Networks (DBN), Convolutional Neural Network (CNN), Stacked Auto-Encoders...

The algorithm reduces the size of the search for the structure inherent in the data. Includes Principal Component Analysis (PCA), Principal Component Regression (PCR), Partial Least Squares Regression (PLSR), Sammon Mapping, Multidimensional Scaling (MDS), Projection Pursuit, Linear Discriminant Analysis (LDA), Mixture Discriminant Analysis (MDA), Quadratic Discriminant Analysis (QDA), Flexible Discriminant Analysis (FDA) ...

Aggregation algorithms are models that consist of weaker models. Includes Boosting, Bootstrapped Aggregation (Bagging), AdaBoost, Stacked Generalization (blending), Gradient Boosting Machines (GBM), Gradient Boosted Regression Trees (GBRT), Random Forest...

3. Applying Machine Learning to Credit Risk Management of Banks

Credit risk is most simply defined as the potential that a bank borrower or counterparty will fail to meet its obligations in accordance with agreed terms. The goal of credit risk management is to maximise a bank's risk-adjusted rate of return by maintaining credit risk exposure within acceptable parameters. Banks need to manage the credit risk inherent in the entire portfolio as well as the risk in individual credits or transactions.

A precise credit risk assessment system is vital to a financial institution for its proper and impeccable functioning. Accurate estimations of credit risk will allow them to continue their operation in a gainful and transparent way. As the rate of loan defaults are gradually increasing, bank authorities are finding it more and more difficult to correctly assess loan requests. Thus, the subject of credit risk has become a highly conferred and examined topic throughout the world. Numerous solutions have been given, ML included. Banks or other loan providers should select only those applicants who have the lowest chance of defaulting. And this is where the power of machine learning and data science comes in.

First, ML comes into play in *screening loan applicants* with the lowest likelihood of default out of the thousands of loan proposals banks receive. According to S. Z. H. Shoumo et al. (2019), ML can be applied in this case to develop a model capable of understanding and learning from the behavioral patterns of successful customers and defaulters. When someone applies for a new loan, the model can accurately predict an applicant's likelihood of default based on patterns it has previously learned, and credit institutions such as banks or other lenders use this result to make decisions whether to accept an applicant's loan request. Khashman, A. (2010) describes a credit risk assessment system using a supervised neural model based on a back propagation learning algorithm. The author trains and deploys three neural networks to decide whether to approve or reject a loan application. Neural networks were trained using a bank loan approval dataset in Germany of 1000 cases (700 cases where applicants are credible "good" or "accepted" and 300 cases are unreliable "bad" or "rejected"), each case has 24 numerical attributes to decide whether each loan application is accepted or rejected. As a result, the overall accuracy rate in credit decision-making was

83.6%; the neural model training was completed in about 184 seconds, while the decision-making time for the trained neural model was very fast. Hamid, A. J. and Ahmed, T. M. (2016) used Bayes-net, Naïve Bayes, and Decision Tree (j48) algorithms for this purpose. Based on borrower characteristics such as gender, credit history, occupation, loan purpose, age, type of housing, and loan amount to predict whether the new applicant will become a defaulter. According to this study, the Decision Tree algorithm (j48) was their preferred choice with an accuracy of 78.3784%.

ML is proven to be superior to traditional methods of predicting credit risk through comparisons between the application of ML's algorithms and traditional methods. Many studies have compared with traditional statistical methods to highlight the effectiveness of applying ML algorithms. Galindo and Tamayo (2000) assert that the only way to assess the risk of financial intermediaries is through the search for reliable predictors of individual risks in the credit portfolio. They compared statistical classification techniques and ML by building more than 9,000 models and comparing the performance of different algorithms. By using various ML algorithms to classify mortgage loan data, the study found that decision-making algorithms provided the best estimate of defaultability with an average error rate of 8.13%, with neurological algorithms providing the second-best results with an average margin of error of 11%, followed by the kNN algorithm and the Probit algorithm. Bekhet, H. A. and Eletter, S. F. K. (2014) used multilayer feed relay neurons and compared with a logistic regression model. They used data on 492 cases collected from Jordanian commercial tendons. The results showed that the regression model was more accurate in properly classifying accepted loan applications, and neural network had an advantage in classifying rejected customer cases. Hamori et al. (2018) studied and compared the accuracy of predictions and the classification capabilities of Random Forest Neural Network the analysis of insolvency data. They also see the superiority of ML methods. Nguyen Minh Kieu et al. (2017) based on collecting data from past records of banks including Vietcombank, Vietinbank, Sacombank, Dong A, MBbank over the period of 2012-2014, applying supervised Artificial Neural Network (ANNs) models based on transmission learning algorithms for the purpose of training to decide on approval or rejection denial of granting credit. Based on the research results, the ANNs model is effective in supporting quick and simple credit decision making with the accuracy rate of forecasts up to 95.45%. The results of the study are similar to the results of Vita Jagric, Davorin Kracun and Timotej Jagric (2011), Adnan Khashman (2010) ... In conclusion, ANNs support quick decision-making with high accuracy.

Much of the research seems to focus on *credit scoring* techniques, as seen in the large number of studies in this area (Ala'raj and Abbod, 2016; Bellotti and Crook, 2009; Cao et al., 2013; Wang et al., 2015; Wójcicka, 2017). These studies mostly focus on the classification and application of credit scoring algorithms. Studies have generally concluded that ML offers comparable accuracy and is better equipped to capture common non-linear relationships of credit risk (Bacham and Zhao, 2017; Hamori et al., 2018; Zhang, 2017). Techniques such as logistic regression and discriminant analysis are often used in credit

scoring to determine default. SVM has been successful in classifying defaulting customers and has been shown to deliver significantly better results in credit scoring (Van Gestel et al, 2003). This algorithm is also said to compete in discovering the most important characteristics in determining default risk when examined and compared to traditional techniques (Bellotti and Krook, 2009). Among the techniques used in credit scoring, such as differential analysis, logistic regression, artificial neural networks, and decision trees neural networks have been shown to perform more accurate classification than the rest of the methods (Yeh and Lien 2009). Harris (2013) compared SVM-based credit scoring models that used broad definitions (overdue dates <90 days) and narrow definitions (overdue dates >90 days) and found that models built using a broader definition were more accurate, thereby allowing improved accuracy of predictions.

ML is also applied to *Stress test* in credit risk management (Islam et al., 2013). Stress test requires modeling the link between macroeconomic development variables and banking operations variables to determine the impact of extreme scenarios on banks. Adaptive Least Absolute Shrinkage and Selection Operator in the supervised H method is used in the absence of theoretical models to test endurance from a set of thousands of specifications. It has been shown to provide non-deviation and approximation solutions by looking for variables that best describe the behavior of credit loss ratios, providing a clear description of the relationship between credit loss ratios and macroeconomics. An important problem when applying this algorithm is that large amounts of data are required to train the model (Blom, 2015). Model selection and forecasting become challenging as stress scenarios become more comprehensive with an increasing number of underlying variables. ML techniques for identifying patterns (patterns) and relationships between data can facilitate model selection and forecasting. These techniques do not appear to have been widely applied in endurance tests. When there are a large number of potential covariants and the number of observations is small, Lasso regression is found to be suitable for building predictive models. These models outperform traditional statistical models in forecasting the performance indicators required in endurance test. They can also handle complications that arise during endurance tests (Chan-Lau, 2017). In addition, the Multivariate Adaptive Regression Splines (MARS) algorithm, another ML technique, also demonstrates greater accuracy in endurance testing with superior samples, providing more reasonable forecasts (Jacobs, 2018). Probabilistic graphs can be used to model and assess credit concentration risk with Bayesian network algorithms (Bayesian Network) provides a better understanding of risk. This algorithm was also found to be suitable for analyzing endurance testing with the ability to provide an estimate of the likelihood of losses due to changes in the borrower's financial condition (Pavlenko and Chernyak, 2009).

4. Conclusion

It can be seen that Machine Learning is useful in credit risk management of banks, especially the first two stages in the risk management process: identification and measurement. The application of ML risk management in general and credit risk management in particular is inevitable. However, the challenges to adoption are not small.

For instance, the challenge of the quality of the data. Data is one of the most important components of an ML model because the performance of the model directly correlates with the quality of the data it is provided. When it comes to the use of AI in general and ML in particular, it is essential to increase the confidence factor for the performance of the model by ensuring that the data used is huge, diverse, and regularly updated. The data collection process should not be taken lightly because building a high-quality dataset requires a lot of time and effort. Or the issue of data security is also a challenge that banks must overcome. The large amounts of data used in these models can be considered very sensitive. The customer's name, age, address, credit card number, bank account, and other information may be included in such data. In these cases, a data breach would jeopardize customers' personal privacy while also allowing attackers to gain access to their financial assets. To solve this problem, it is necessary to take additional security precautions to prevent sensitive data from falling into the wrong hands. Next, it is impossible not to mention the legal challenge. This is an issue that has been talked about a lot since new financial technologies spread and are applied in the provision of financial services and banking.

Abstract

This paper examines farmers' current access and desired use of seasonal forecast and advisory service as well as their intention to use digital climate advisory service (DCAS) in the Mekong River Delta of Vietnam. Data collected through a survey of 665 farmers showed that access to seasonal climate advisory service was quite high for farmers primarily engaging in rice, fruit and rice-shrimp farming, with over 50% of farmers in these systems could access to this service. Rice and rice-shrimp farmers, in particular, have significantly greater access than rice-shrimp farmers. The main sources and channels utilized by farmers to obtain such information were TV/Radio, other farmers/family members, local authorities, and cooperatives. Variations were observed in sources and channels employed to obtain seasonal forecast and advisory service among farming systems. Fruit farmers had higher access to this service through other farmers/family members and phones; while rice farmers relied more on cooperatives and are more likely to access this service via village loudspeakers. Rice-shrimp farmers, on the other hand, displayed a higher likelihood of obtaining seasonal forecast and advisory for shrimp from input providers. The study revealed that the surveyed households commonly owned TVs, smartphones, and basic phones. The proportion of smartphone usage among the respondents (68.78%) was comparable to the smartphone penetration in rural areas (68%), but slightly lower than the nationwide rate (73.5%). The respondents demonstrated a preference for interactive channels with visual aids which was not supported by their current sources and channels of seasonal forecast and advisory. However, they showed a neutral stance toward using digital tools to access DCAS without guidance. While farmers in our survey recognized the potential benefits of DCAS, their inclination to use a phone to access such services remained neutral. In our survey, male respondents expressed a higher intention to use DCAS.

Keywords: *digital climate advisory services (DCAS), seasonal forecast and advisory, intention to use*

1. Introduction

While being one of the main agricultural production zones in Vietnam, the Mekong River Delta region is particularly susceptible to the impacts of climate change (ADB, 2009; WWF, 2009). That leads to an increasing need for solutions to help farmers in the region adapt and improve their agricultural practices. Climate Advisory Services (CAS), more specifically seasonal forecasts and advisories, have emerged as one potential solution.

CAS entails the generation, distribution, and contextualization of climate knowledge and information to assist decision-making (Vaughan & Dessai, 2014). In the agricultural sector, these services offer weather and climate forecasts, crop management advice, pest and disease alerts, and other bundled information such as insurance, market, and input (Ferdinand et. al. 2021).

One type of CAS, which is the focus of this study, is seasonal forecast and advisory service for farmers. Based on anticipated weather and climate conditions for a specific period, such as a growing season or planting season, this service assists farmers in making informed decisions and adjusting their agricultural practices accordingly. For example, it can provide weather forecasts and crop management advisory for the whole season, allowing farmers to plan their activities, such as crop selection, planting dates and manage their crops to minimize risk and optimize yields.

Digital CAS, more specifically in this paper, seasonal forecast and advisory service, can take the form of online tools and platforms such as websites, mobile applications, mobile messaging, products or bulletins that make use of Information Communication Technologies (ICTs) to provide on-time and tailored climate-related information and knowledge for decision making (Vaughan & Dessai, 2014). Easy and timely access to decision-relevant scientific climate-related information can assist users, particularly vulnerable ones, in making use of favorable climate conditions and coping with and building resilience to climate-related disasters.

In Global North, CAS are typically initiated and provided by private actors, such as multinational ag-tech, big tech companies, and start-ups. On the other hand, in Global South countries, the stakeholders that are mainly involved in CAS delivery are government, international donors, nonprofits and research organizations through projects (Simelton & McCampbell, 2021). In Global South, in particular, a great deal of discussion has revolved around how to “bring tailored and actionable climate information to the ‘last mile’ - the small-scale agricultural producers and actors in the food value chain” (FAO, 2021, p.ix). It is critical to address this challenge as the last-mile farmers are those most vulnerable to the impacts of climate change while being the backbone of global food security.

In Vietnam, CAS has become an emerging topic in the climate change adaptation agenda. Given the high Internet and smartphone penetration rates as well as the fact that the agricultural sector makes up 14% of the GDP and employs 40% of the total workforce in Vietnam (ILO, 2021), there is a promising market for this service in Vietnam. The research topic about digital CIS also aligns well with the digitalization trend in Vietnam’s economy.

In recent years, the Vietnamese government has prioritized the development of a digital economy, recognizing its potential to drive innovation, competitiveness, and sustainable growth (Vietnam's Government, Decision No. 749/QD-TTg). Thus, there is a growing interest in the role of digital technologies in agriculture, and the potential for digital CAS to support climate adaptation and mitigation in the Mekong River Delta.

In Vietnam, government actors play crucial roles in delivering CAS. The Ministry of Natural Resources and Environment (MONRE) has the responsibility for state management over climate service delivery in Vietnam, as mandated by the Law on Hydro-meteorology. The Viet Nam Meteorological and Hydrological Administration (VMHA) is responsible for providing public weather forecasts, managing the national hydrological monitoring system, as well as providing free public weather forecast and information or data for individuals and organizations upon request with fee (Care International, 2020). In agricultural sectors, the Ministry of Agriculture and Rural Development (MARD) will utilize the forecast and information shared by VMHA to provide recommendations on crop planting and management for farmers through its support services. Local authorities at different levels, including provincial, district, and communal levels, closely collaborate with relevant organizations such as local plant protection departments and agricultural extension centers to deliver CAS to farmers.

This paper is timely and relevant, given the increasing impacts of climate change in the Mekong River Delta. By exploring farmers' access to and intention to use digital seasonal forecast and advisory, our paper will provide insights into how to design the service that cater to farmers' needs.

2. Method

2.1. Overview of survey design and implementation

To inform this study, the field survey of farming households is the key methodology. The study was conducted in four provinces in the Mekong River Delta region of Vietnam, namely **Can Tho, Hau Giang, Kien Giang, and Soc Trang**. The selection of these provinces was based on several criteria to ensure the best representation of the agroecological zones, prioritized farming systems, and climate risk and vulnerability.

Firstly, the provinces were selected based on **the three agroecological zones**: freshwater, salt-brackish water, and transition areas, as defined by Decision 287/QD-TTg 2022. Can Tho and Hau Giang provinces were selected because they are situated in Zone 1, which is a freshwater area. Soc Trang and Kien Giang provinces were selected because they belong to all three zones.

Secondly, the **prioritized farming systems** for this study were rice, rice-shrimp, and fruits. Can Tho, Hau Giang, and Soc Trang provinces were selected for the rice and fruit systems as they have large areas of rice and fruit farming. Kien Giang and Soc Trang provinces were selected for the rice-shrimp system.

Lastly, provinces were selected based on **climate risk and vulnerability**. The risk of salinity intrusion along the main rivers was considered. Hence, provinces located along the

Hau River connecting with the East Sea (Can Tho, Hau Giang, and Soc Trang) were chosen. Kien Giang province was selected to represent salinity intrusion risk from the other seaside (Thailand Gulf).

Based on the common formula suggested by Cochran (1963), a sample size of 600 participants was identified for the study:

$$n_o = \frac{Z^2 pq}{e^2} = \frac{(1.96^2). (0.5). (0.5)}{(0.04)^2} = 600$$

Where, n_o is the sample size, Z is the abscissa of the normal curve that represents level of confidence, p is the estimated proportion of an attribute that is present in the population, q is $1-p$, and e is the sampling error. Z -squared is equal to 1.96 with a confidence level of 95%. If we assume the adoption level p is 0.5 and the sampling error e is 0.04, then the calculated sample size is 600.

However, our study did not only rely on the common statistical formula to determine the sample size due to two main reasons. First, the research questions in the study focused on farmers' perception of climate services quality and readiness to use digital climate services, which were measured using Likert-scale questions. These questions cannot be quantified in real numbers. Second, to achieve high-quality outputs, non-linear modeling techniques, such as structural equation modeling, were likely necessary for data analysis. To address our research needs, we undertook a rigorous literature review in order to learn about possible sample sizes in relevant previous studies. The relevant studies were selected based on criteria that they were similar to our study in terms of (i) research topics (ii) research context/location (iii) data analysis techniques. The literature review indicated the range of sample size from 450 to 690 farmers. In the end, our sample size was 665 farmers.

The survey was undertaken from December 19 to 30, 2022, in Can Tho, Kien Giang, Soc Trang, and Hau Giang provinces, using tablets with questionnaires coded on KOBO toolbox. A total of 667 responses were collected, of which two were identified as duplicates and removed, leaving a final dataset of 665 responses. Of these, 68% were male and 32% were female. The table below summarized the sample breakdown by provinces and farming systems.

Table 1. Sample breakdown of the study

Province	Farming system			Sub-total by province
	Rice	Fruit	Rice-shrimp	
Can Tho	59	84		143
Hau Giang	60	81		141
Kien Giang	51	0	150	201
Soc Trang	50	80	50	180
Sub-total by farming system	220	245	200	665

2.2. Characteristics of the sample

Table 2 presents the demographic characteristics of surveyed respondents. We also investigated the differences in demographics between farming systems. ANOVA and Chi-square tests were applied to see if the differences between interested groups are statistically significant.

The results of ANOVA and Chi-square tests show **significant differences** among the three farming systems in terms of **land, farming experience, number of vehicles/machines owned by household, ethnicity, gender, and education level.**

Rice (M = 2.00ha) and fruit (M = 1.87ha) farmers have more arable land than rice-shrimp farmers (M = 1.40ha), $p < 0.001$

Rice farmers (M = 27.29 years) have more farming experiences than fruit (M = 9.96 years) and rice-shrimp farmers (M = 9.45 years), $p < 0.001$

Fruit farmers (M = 113.8 mil VND) earned more than rice farmers (M = 96.1 mil VND) in 2022.

Fruit farmers are more likely to own a high school degree or higher than rice and rice-shrimp farmers ($p < 0.017$)

Table 2. Demographic characteristics of surveyed respondents by farming system

Variable	Whole sample N = 665		Rice N = 220		Fruit N = 245		Rice-shrimp N = 200		P-value
	Mean / %	SD	Mean / %	SD	Mean / %	SD	Mean / %	SD	
	Age	51.30	11.67	50.52	11.67	50.52	11.67	52.45	
Household member	4.37	1.66	4.40	1.58	4.40	1.58	4.27	1.72	NS
Members working on the farm	2.26	0.96	2.29	1.05	2.29	1.05	2.16	0.83	NS
Average agricultural land (own + rent)	1.77	1.51	2.00	1.48	1.87	1.70	1.40	1.19	< 0.001
Farming experiences (year)	15.54	12.62	27.29	13.15	9.96	6.68	9.45	7.64	< 0.001
Income 2022 (mil VND)	104.35	69.62	96.14	66.61	113.76	74.03	101.85	66.19	0.02
Educational level									0.017
Lower than high school	79.70%		82.70%		73.90%		83.50%		
High school and higher	20.30%		17.30%		26.10%		16.50%		

3. Results

3.1. Farmers' current use of seasonal forecast and advisory service

Seasonal forecast and advisory service provides climate forecast for 3-6 months, with recommendations on planning and crop management for the whole season. In Vietnam, seasonal forecast and advisory are often provided by the Government and/or non-governmental organizations (NGOs). Example of seasonal forecast and advisory is the seasonal calendar on planting dates and rice variety structure or “Lịch thời vụ và cơ cấu giống lúa” in Vietnamese provided by provincial departments of agriculture and rural development. These calendars often include an assessment of hydrological conditions, water availability, and weather forecasts for the whole season, along with specific advice on planting date, harvesting time and varieties used to optimize their rice cultivation outcomes. Another example of seasonal forecast and advisory provided by NGOs is the Seasonal Agro-Climatic Bulletins for rice, vegetables, and dragon fruit, provided by DeRisk SE Asia project. These bulletins encompass weather forecasts for the entire season, assess the potential impact of extreme weather events on selected crops in different cropping stages, and provide recommended farm management practices to mitigate such impacts.

Overall, **access to seasonal forecast and advisory** is high, with 68.42% of surveyed farmers receiving or actively this service. 16.99% didn't have access but would like to, while 14.59% indicated not being interested in this type of service. Among the three priority farming systems, there is a significant difference in access to seasonal forecasts and advisories. Results of chi-square tests show that rice farmers (82.37%) and rice-shrimp farmers (70.50%) have significantly higher access to this service than fruit farmers (53.88%) ($p = 0.003$, $p < 0.001$)

Figure 1. Access to seasonal advisory service by farming system

While only 8%-11% of rice and rice-shrimp farmers are not interested in seasonal forecasts and advisories, 23.67% of fruit farmers indicated not being interested. The three most common reasons for not being interested in the seasonal forecast and advisory services are that farmer can rely on their experience, they need to follow certain practices for each group growth stage, and they do not know the source/provider of the service. Fruit farmers are more likely to choose “I have to follow certain practices for each crop growth stage anyway” than farmers in other systems.

With regards to the **type of information** that farmers are most interested in when seeking seasonal forecast and advisory, data from the survey show that:

- The top 3 types of information interested by **rice farmers** are **advice on planting dates, varieties to plant, and weather forecast** for the whole season.

- For **fruit farmers**, the top 3 most interested types of information are **fertilizer application, when to start a new season, and pest and disease management** for the whole season. However, unlike rice-rice and rice-shrimp farmers, they are less interested in advice on planting dates and varieties to plant, with nearly 40% choosing these types of information, compared to nearly 90% for rice and rice-shrimp farmers.

- **Rice-shrimp farmers** are most interested in the **advice on shrimp fingerling to stock and stocking date, agrochemical and medicine for shrimp, shrimp feed, and weather forecast** for the whole season. Only a small percentage of rice-shrimp farmers expressed interest in advice on water management and fertiliser application for mixed rice-shrimp systems for the whole season. It is possible due to the low prevalence of this type of farming among the surveyed rice-shrimp farmers (only 3.5% practice mixed rice-shrimp farming) and the fact that farmers often don't apply fertilizer for mixed rice-shrimp farming.

Concerning **sources/channels** of seasonal forecast and advisory, farmers in the three farming systems commonly access seasonal forecast and advisory via **TV/Radio, other farmers/ family members, local authorities and cooperatives** with around 40% reported using these channels/sources.

- Overall, among those who have access to seasonal forecast and advisory services, **other farmers/family members (54.29%), TV/radio (50.99%), local authorities (40.89%), cooperatives (36.70%), and phone (31.87%)** were commonly used channels/sources. In terms of phone, surveyed farmers obtain seasonal forecast and advisory from Google, Youtube and Zalo.

- The results of Chi-square tests revealed significant differences in the accessibility of seasonal forecast and advisory service among the three farming systems via **other farmers/family members, cooperatives, phone, input providers and village loudspeakers**. Specifically, fruit farmers were more likely (62.12%) to obtain seasonal forecast and advisory from other farmers/family members compared to rice farmers

(45.60%) ($p = 0.008$). Rice farmers had a higher likelihood (52.75%) of accessing this service through cooperatives compared to fruit farmers (23.48%) and rice-shrimp farmers (28.37%) ($p < 0.001$). Fruit farmers were more likely (41.67%) to receive this advisory through the phone than farmers in the other systems ($p = 0.016$). Rice-shrimp farmers (28.37%) had a higher likelihood of obtaining seasonal forecast and advisory for shrimp through input providers, while rice farmers were less likely to do so ($p = 0.001$). Rice farmers (14.84%) had higher access to this service via village loudspeakers compared to fruit farmers (3.79%) and rice-shrimp farmers (4.26%).

• **For those who don't have access but would like to** receive Seasonal forecast and advisory: **TV/radio** (54.87%), **phone** (34.51%), **local authorities** (38.94%), and **other farmers/family members** (30.97%) are the most preferred sources.

In relation to **lead-time**, refers to how far in advance the farmers actively seek or need seasonal forecasts and advisories to prepare for their upcoming crop. Overall, a **2 - 4 week lead time** is most preferred by the surveyed respondents. Results of the chi-square test revealed a significant difference in preferred and current lead time among the three farming systems ($p < 0.001$). Specifically, rice farmers prefer a lead time of less than 2 weeks (40.90%) or 2-4 weeks (40.90%) to make plans for the upcoming season. Similarly, rice shrimp farmers need seasonal forecasts and advisories less than 2 weeks or 2 - 4 weeks to prepare their shrimp. Fruit farmers, on the other hand, prefer a longer lead time (2-4 weeks or 1-2 months).

Regarding **farmers' perceived quality** of seasonal forecast and advisory, the farmers surveyed generally find this service to be relevant ($M = 3.99$), timely ($M = 4.06$), and having good quality ($M = 3.99$). Results of Wilcoxon-signed tests show there are significant differences in Relevance, Timeliness, and Overall quality ratings of Seasonal advisory among three farming systems. Rice farmers ($M = 4.08$) and rice-shrimp farmers ($M = 4.06$) perceive seasonal forecasts and advisories more relevant than fruit farmers ($M = 3.80$), $p = 0.004$ and $p = 0.001$ respectively. Rice farmers ($M = 4.19$) and rice-shrimp farmers ($M = 4.10$) perceive seasonal forecasts and advisories more timely than fruit farmers ($M = 3.84$), $p = 0.001$ and $p < 0.001$ respectively. Rice farmers ($M = 4.06$) and rice-shrimp farmers ($M = 4.04$) perceive seasonal forecasts and advisory as having higher overall quality than fruit farmers ($M = 3.85$), $p = 0.026$, and $p = 0.010$ respectively.

3.2. Farmers' intention to use digital climate advisory service

This section focuses on farmers' digital device ownership and behavior and their intention to use digital climate advisory services (DCAS).

Concerning household ownership of digital devices, three digital devices that are mostly owned by the surveyed households are **TV (95.49%)**, **Smartphone (94.44%)** and **Basic phone (60.75%)**. For respondents that have TVs at home, 63% reported that they can access the Internet via this device.

For respondents that have smartphones at home, **62% reported using the smartphone**, 27.17% said that the phone was used by other household members, and 10.83% shared with other household members. Among respondents that have a basic phone at home, **71.95% of those who had basic phone at home reported using this device**, 23.12% said that the phone is used by other household members and 4.94% share it with other household members.

The survey results revealed that 68.78% of the respondents reported using smartphones. This percentage aligns closely with the smartphone penetration rate in rural areas, which stands at 68% (Mobile Marketing Association, 2019). However, it is slightly lower than the nationwide smartphone usage rate of 73.5% (Ministry of Information and Communications, 2022).

74% of respondents reported paying for an online monthly subscription, which is mostly for WIFI and/or TV packages. Results of Chi-square tests show that there are significant differences in household ownership of digital devices among farming systems. Specifically, fruit households are more likely to own a smartphone ($p = 0.002$) and a laptop ($p = 0.014$) than households in other farming systems.

Table 3. Household ownership of digital devices

Unit: %

	TV	Radio	Basic phone	Smart phone	Tablet	Computer	Laptop
Household ownership (whether the respondent has the device at home)	95.49	11.13	60.75	94.44	8.87	5.56	16.54
% of respondents use the device they have at home	7.25	58.33	71.95%	62.00	8.77	22.22	10.19
% of respondent whose other HH members use the device	2.64	18.06	23.12	27.17	85.96	69.44	83.33
% of respondents share the device with other HH members	90.12	23.61	4.94	10.83	5.26	8.33	6.48
Internet access via the device	63,0	2,0	3,0	99,0	100	100	100

To support their farming activities, respondents use their digital devices mostly to check weather forecast (59.37%), which is followed by seeking crop advisory (41.79%) and searching input prices (41.49%), obtaining market information (35.16%). However, very few respondents (3.65%) use it as a market-place to sell their products.

Figure 2. Farmers' use of digital devices for farming activities

To examine farmers' intention to use DCAS, we presented them with a scenario in which a paper seasonal forecast and advisory bulletin were being digitized and asked them to rate their intention to use it on a scale from 1 (Very unlikely) to 5 (Very likely). 31.7% held relatively neutral opinions about their intention to use the digital climate advisory bulletin. Overall, respondents were relatively neutral regarding their intention to use the digital climate advisory bulletin ($M = 3.21$). 12.8% and 10.7% are very unlikely and unlikely to use DCAS respectively. 32.2% and 12.6% are likely and very likely to use DCAS respectively. Results of the t-test show that male respondents ($M = 3.33$) are more likely to use DCAS+ than female respondents ($M = 2.97$) ($p < 0.001$).

Table 4. Respondents' Intention to use digital climate advisory services (DCAS)

Intention to use	Mean	SD
Whole sample (N = 665)	3.21	1.18
Rice (N = 220)	3.26	1.20
Fruit (N = 245)	3.16	1.17
Rice-shrimp (N = 200)	3.23	1.18

The most common reason for not intending to use the digital bulletin is difficulty accessing climate and agricultural advisory through digital channels, followed by the fact that they can rely on existing sources of information and lack of digital devices.

4. Conclusion

The study provided insights into farmers' current access to seasonal forecast and advisory service as well as their intention to use DCAS.

Regarding the current access to seasonal forecasts and advisories, rice farmers and rice-shrimp farmers have significantly higher access to this service than fruit farmers. In

terms of sources and channels used to access this service, farmers commonly rely on TV/Radio, other farmers/family members, local authorities, cooperatives.

The study results indicate disparities in access to seasonal forecast and advisory service among different farming systems. Fruit farmers have higher access to this service through other farmers/family members and phones compared to rice farmers. Rice farmers, on the other hand, have greater access to this service through cooperatives and village loudspeakers. Rice-shrimp farmers demonstrate a higher likelihood of obtaining seasonal forecast and advisory for shrimp from input providers.

The surveyed households commonly own TVs, smartphones, and basic phones, with a lower proportion of smartphone usage among respondents than the national average in Vietnam. Among the individuals surveyed, the proportion of smartphone usage is comparable to the rate of smartphone adoption in rural areas, though slightly lower than the overall national rate. The findings indicate significant smartphone adoption among the surveyed population, reflecting the increasing prevalence of mobile devices in rural areas. Although slightly below the nationwide average, it highlights the potential for leveraging mobile technology in rural contexts.

The surveyed farmers prefer interactive channels with visual aids but are neutral about using digital tools without guidance. They see the potential benefits of DCAS, but they are neutral regarding intending to use a phone to access the it. Male farmers expressed a higher intention to use DCAS than female.

EVALUATIONS OF E-WALLETS IN VIETNAM FOR SUSTAINABLE DEVELOPMENT TARGET

Dr. Nguyen Minh Phuong

phuongnm@hvn.edu.vn

Faculty of Banking, Banking Academy, Hanoi, Vietnam

Abstract

To meet the needs of today's consumers, Fintech companies have been establishing a payment ecosystem via e-wallets. This is in line with the Government's policy of developing non-cash payments. It can be seen that, one of the most special marks in the payment market in the past 5 years is the emergence of E-wallets. The article will describe the current situation of E-wallets of Vietnam in recent times, make some comments, evaluate and propose some policy suggestions.

Keywords: *E-wallets , Vietnam, non-cash payment, Fintech*

1. Introduction

The 4th technology revolution along with the impact of the Covid-19 epidemic has promoted electronic payment forms, the E-wallet market has also become more and more exciting. According to statistics, the number of people using E-wallets and cashless payment applications has increased sharply recently, especially since the Covid-19 pandemic. To the latest data from the State Bank of Vietnam, more than 200 million transactions were carried out through E-wallets, with a value of about VND 77.7 trillion in the first months of 2021 (MOF, 2021). This is the result of the growing trend of online shopping and people's interest which focus on safety and reducing the risk of disease transmission. Credit institutions and banks in Vietnam have also actively cooperated with many Fintech companies to accelerate digital transformation in the banking sector, providing safe and convenient products and services at affordable prices and suitable for customers.

Customer satisfaction is an extremely practical factor that ensures customer loyalty to a certain product, service or brand, which determines the existence of any brand. Ira. P, Alvin. N and Purbandini. S (2021) stated that Indonesians use E-wallets because of their convenience, security and advantages over cash when the number of E-wallets have grown to more than 50 providers by 2020 in this country.

The study "Customer Expectations in E-wallet Service" by Muhammad Asyraf Hasim, Sanusi Abdul Manaf and Aeshah Mohd Ali (2020) adds another important factor that is that brand image and price have almost no influence. Their survey conducted through the internet to reach out to different social groups to be more objective. Based on data obtained from 500 responses, the author concludes that service quality, brand image and trust are the 3 most important factors affecting the satisfaction and loyalty of wallet users. Ahmad

Daragmeh et al (2021) published a study on named "Continuous Intention to Use E-Wallet in the Context of the COVID-19 Pandemic" to predict the factors that strongly influence consumers". From the research, in the short term, decision makers need to take advantage of the health concerns to use e-wallets as it is considered a factor to help protect consumers themselves from harm. disease through non-contact. In the long term, commercial banks should develop strategies to increase consumer loyalty to e-wallet products.

2. Context framework

The study will use the qualitative method to accessing the situation of E-wallets in Vietnam. Firstly, regarding the current status of E-wallets development in Vietnam, it can be seen that after 10 years of development, E-wallet has become popular with users, but there are still many gaps and potential to exploit. The government is required to support the development, create conditions for payment intermediaries to innovate, actively contribute to the promotion of non-cash payments, and manage and orient the market in the right direction. So, at the end of 2019, the State Bank of Vietnam issued Circular 23/2019/TT-NHNN amending Circular 39/2014/TT-NHNN guiding intermediary payment services with many new points to create favorable conditions for payment as well as enhancing security, protecting users' interests.

According to Circular 23/2019/TT-NHNN, customers are allowed to connect identity-verified E-wallets with multiple payment accounts, and debit cards, allowing them to maintain multiple wallet accounts. In addition, to ensure safety, prevent fraud, and money laundering, and protect the interests of customers, organizations providing e-wallets must comply with the provisions of the circular on opening and maintaining digital wallets...

These new regulations have received quite positive feedback after a period of implementation. In the first 6 months of 2021, e-wallet activities have achieved very positive results. Specifically, according to statistics from E-wallet service providers, the total number of successfully processed E-wallet transactions increased by 85.38% in the number of transactions and 91.57% respectively from 2021 to 2022. (Statista, 2022).

Secondly, about the trends of using E-wallets in Vietnam. According to a survey by Visa, in the context of the Covid-19 epidemic, Vietnamese consumers are gradually choosing to use E-wallets as well as contactless payments and payments with QR codes. The survey also shows that 57% of consumers have up to three E-wallet apps on their phones, and 55% of consumers prefer an app that can do all transactions. According to the data of Vietnam National Payment Joint Stock Company (Napas) announced in 2020, non-cash payment transactions via Napas reached more than 1.2 billion transactions, equivalent to 10 million billion VND, the corresponding growth of 75% in quantity and 121% in value compared to 2019. The proportion of cash withdrawal transactions at ATMs via Napas also decreased from 42% in 2019 to 26% in 2020.

Figure 1. Popular transactions of customers using e-wallets

Source: Decision Lap (2021)

Momo, ShopeePay (AirPay), and ZaloPay are the top three most popular E-wallets in the market, based on penetration rates (Decision Lap, 2021). Simultaneously, the study also showed that E-wallets are used the most to recharge phones, transfer money, pay periodic bills, pay for food delivery services, and order technology cars. In which, Momo and ZaloPay are used the most to recharge phones, transfer money and pay periodic bills. Moca is mainly used for the needs of technology car payments, phone recharges, money transfers, and food delivery. The research results also show that the usage frequency and average daily consumption value of popular E-wallets on the market are both at a high level. Specifically, consumers spend an average of 230,000 - 274,000 VND/transaction. In which, Moca users are currently using the wallet most often. On average, Moca users make 2.2 transactions per day, Momo users make 2 transactions and ZaloPay users with 1.6 transactions.

Figure 2. The growth of Vietnam's E-wallets market

Source: Vietnamnet.vn (2021)

As of July 2021, the number of E-wallets of payment intermediaries in Vietnam is up to 43 firms with a population of more than 97 million people, not to mention E-wallets of banks. Thus, the number of E-wallets has increased 7 times compared to 2015.

3. Results

The study will evaluate the current situation of E-wallets in Vietnam in terms of opportunities and challenges.

In terms of opportunities

First, the Government of Vietnam set a target: "The ratio of cash to total means of payment at 8% by 2025". Along with that, due to the impact of the Covid-19 epidemic, consumers have changed their habits of using cash in payment, instead buying goods and paying online to limit contact and spread of the epidemic".

Second, vendors update many new features for E-wallets to increase their market share. In addition to QR scanning payment technology, some E-wallets apply QR scanning technology to create a new experience for customers. It can be seen that the 4.0 technology revolution contributes to creating many opportunities for the development of electronic payment forms in general and E-wallets in particular.

Third, at present, the number of people using smartphones and using the Internet through these devices has increased significantly. The number of Internet users in Vietnam ranks 12th worldwide and 6th out of 35 countries/regions in Asia. On average, Vietnamese spend about 7 hours a day, up from 2020 (5.1 hours/day) connecting to the Internet via mobile, and 94% of Internet users use the Internet daily. Through the statistics, we can see that in Vietnam, it is difficult for users to separate Internet-related activities for more than a week. The impact of Covid 19 and the time of social distancing has changed habits and increased interaction time with smart electronic devices. This is an opportunity to increase the number of E-wallet users in the future.

Fourth, E-commerce has been a familiar transaction method of many large trading companies in the world and is growing, becoming familiar to users in Vietnam. This method changes the buying and selling habits of consumers. Payment by cash has decreased from 86% to 78%, while the proportion of payment via e-wallets and cards has increased slightly compared to previous years. Thus, with the explosion of e-commerce, the E-wallet market will have great opportunities to grow more and more shortly.

In terms of challenges

Firstly, changing the spending habits of Vietnamese people is not easy. In recent times, more and more E-wallets appear and with the Covid-19 pandemic to reach more customers. However, in general, the habit of paying in cash of Vietnamese people is still undeniable, and there is a fear of fraud and risks in the payment process, so a part of people still choose payment in cash. On the other hand, the lack of flexibility and versatility when each type of E-wallets integrates a few similar features is also a common

barrier that makes the rate of use of E-wallets in Vietnam still low. Therefore, how to nurture customer's new habit and convince them to continue using when there is no promotion is what E-wallets need to make more effort.

Second, user acquisition costs are high but the average user transaction value is low. Despite the high rate of mobile payments, the average transaction value per user in Vietnam is still very low. "Developed countries like the US, UK, Norway, Italy have lower mobile payment rates than Vietnam, but the average transaction amount of customers in these countries is much higher. Americans spend an average of nearly \$8,000 on mobile payments, while Britons spend more than \$7,000. At the same time, in Vietnam, consumers only pay an average of about 21 USD via E-wallets. This proves that Vietnamese transactions are only payments for daily consumption. The payment value of each Vietnamese person is so low, but this electronic payment segment "consumes" a large amount of investment capital. It is not difficult to understand that the top Wallets have been reporting losses for many years, for example MoMo lost 854 billion VND in 2019, double the loss in 2018. However, to maintain the user growth rate and serve the next funding rounds, no business has given up this expensive "game", and the prospect of loss may continue to linger.

Third, users are subject to risks related to network security while performing online transactions using E-wallets. "This is a challenge that could hold back the future development of E-wallets. In fact, worrying about the risk of losing money, stealing personal information, and fraud has not stimulated consumers to use E-wallets immediately. In addition, fear of being attacked by hackers or facing an attack of malware, and data leakage are also reasons why consumers feel insecure when using this payment method. Besides, an internet connection is a big obstacle for users to use E-wallets because the availability of e-wallets depends on the internet to work and devices such as tablets or mobile phones. Users will not be able to access the E-wallets if the phone runs out of battery or has no internet" (Y.Meikeng, 2019). The last but not least, the E-wallets market is a problem of the legal corridor. Currently, many subjects have taken advantage of the loopholes of the E-wallets to commit fraud to appropriate property, or even carry out illegal activities through the E-wallets such as money laundering, and betting.

4. Discussion and conclusion

E-wallet is undeniably trend around the world. E-wallet satisfies many needs of users with diverse features to minimize time and cost, quick and simple payment, especially the accompanying incentives. Along with the development of diverse features, and expanding the ecosystem, E-wallet is increasingly difficult to control fraud and scams....so competent authorities need to take measures to tighten the management legal framework and establish a legal corridor to prevent legal loopholes.

First, some recommendations to the Government:

The government needs to have strict regulations for cases where the payment service provider hides fraudulent activities such as money laundering and betting. Issuing strict conditions with the procedures for which payment units open E-wallet accounts for new customers according to Circular 23/2019/TT-NHNN.

Second, some recommendations to the State Bank:

Completing the policy and legal corridor in the form of payment by E-wallets. The State Bank needs to coordinate with agencies and ministries to build and complete the legal corridor in the field of non-cash payment in general and Fintech in particular based on ensuring the harmony of interests between the different stakeholders. Fintech companies, banks, and legal interests of customers.

Policy on infrastructure development, building a digital payment ecosystem such as upgrading interbank electronic payment system, developing switching system, integrating and synchronizing payment technical infrastructure, Banking application with other industries and service areas.

Actively monitor the electronic wallet payment service system, and non-cash payment at commercial banks to provide solutions if there are risks.

Conduct training sessions, and seminars to guide society to understand the direction, policies, and guidelines of commercial banks.

Strengthen communication with users, so that customers can understand the principles of security, and how to use them by the instructions of banks and payment intermediary service providers to ensure real performance money transfer payment transactions and related services safely and securely.

Third, some recommendations for commercial banks

Currently, E-wallets of Fintech companies have become familiar to customers. Therefore, commercial banks, with their important role in the system of credit institutions and the economy, need to promote marketing activities, and increase product and service recognition for customers so as not to be deceived. lost market share to Fintech companies. Commercial banks need to continuously upgrade and improve modern technologies in payment activities. It is extremely necessary to coordinate with payment units, and product and service providers to integrate their information technology with the payment systems of banks.

Partnering with financial technology companies can bring great advantages to banks. Commercial banks need to change the way they operate and diversify their utilities. Currently, banks and companies providing E-wallets services are linked with each other. This is shown in that the customer must have a bank account, money from the bank account will be loaded into the E-wallets, and money transfer, deposit, or withdrawal must go through the bank. This is a premise for cooperation between banks and companies providing convenient services, ensuring the supply of quality products to customers.

USING INFLUENCER MARKETING TO PROMOTE VIETNAM TOURISM

Tran Thi Tuan Anh
anhttt.2411@gmail.com

National Taipei University of Technology, Taiwan

Abstract

The prevalence of electronic commerce has given rise to the emergence of influencer marketing which are playing an important role in attracting customers not only in e-commerce businesses but also in the field of tourism. Influencers become effective marketing strategies to promote travel destinations of many countries across the world. And Vietnam has recently also witnessed the meteoric rise of influencer marketing, capturing the attention businesses and consumers. On the basis of analyzing the current situation of influencer marketing in Vietnam, the article proposes several observations and suggests some solutions to improve this activity for coming years.

Key words: *influencers, influencer marketing, travel promotion, tourist, Vietnam tourism*

1. Introduction

The digital revolution has encouraged consumers to connect, communicate, and interact with each other on convenient and accessible platforms such as Facebook, Twitter, Tiktok..., leading to a huge change in marketing strategies for tourism. With the development of new technologies, tourists are currently able to search travel information much easier on the internet. Information that consumers gain from interpersonal sources has stronger effects on consumer decision-making than traditional advertising techniques (Goldsmith and Clark 2008). As a result, the popularity of influencer marketing, which involves the use of travel social influencers, has increased in the tourism industry (Yilmaz et al., 2020).

Before the COVID-19 pandemic, Vietnam was a popular destination for tourists due to its diverse landscapes, rich culture, and delicious cuisine. Many influencers created attractive content in popular tourist destinations like Hanoi, Ho Chi Minh City, Halong Bay, Hoi An, and other cities across Vietnam. However, with the travel restrictions and safety measures implemented over the whole country in response to the pandemic, the influencer marketing scene for tourism in Vietnam has been affected. Many travel influencers had to postpone their trips or cancel their plans altogether. Despite the challenges, influencer marketing in Vietnam over past years still keeps developing and travel influencers have adapted to the current situation by creating informative and inspiring content from different topics and helping to recover Vietnam tourism.

Although the significance of understanding influencer marketing strategies becomes a crucial concern in the development roadmap of Vietnam tourism, a few researchers are focusing on this issue. Therefore, this article aims to explore the current situation of using

influencer marketing to promote Vietnam tourism, and then suggest some recommendations to help this marketing strategy gain more success in the future.

2. Conceptual Framework

2.1. Influencers

According to Brown & Hayes (2008), influencers are third parties that have significant impacts on a customer's purchasing decision and are responsible for such influences. They described influencers as being similar to consumers who have a direct impact on their followers' behaviors.

De Veirman et al (2017) define influencers as people who are content creators and accumulated a solid base of followers. Through blogging, vlogging or creating short-form content, they provide their followers an insight into their personal, everyday lives, their experiences and opinions. Influencers build a large network of followers and are considered as trusted tastemakers in one or several niches. By involving influencers, brands aim to stimulate influencers to endorse their products and through this way build up their image among influencers' often huge base of followers.

Based on Wikipedia, influencers are influential people on social networks and have a large number of followers. Influencers can come from many different fields and industries, not only artists, doctors, entrepreneurs or celebrities in general, but any individual can become an Influencer if they meet a certain criteria.

Basically, influencers are people who possess qualifications, expertise or social effects on their field. Influencers are also people who impact a large number of followers (from a few thousand to several million). With the trust of the public as well as the followers, influencers will have positive effects on consumers' perceptions of brands and products, leading consumer purchase intention. Influencers will help businesses obtain the trust of targeted customers more easily and convince them to choose advertised products /services.

2.2. Influencer marketing

Influencer marketing is a marketing strategy that uses the influence of key individuals or opinion leaders to drive consumers' brand awareness and/or their purchasing decisions (Brown and Hayes 2008; Scott 2015). According to the Center for Influencer Marketing, influencer marketing is the process of identifying, researching, engaging, and supporting people who create high-impact conversations with customers about brands, products, and services.

Forbes (2018) defines influencer marketing as a type of marketing that focuses on using key leaders to get your brand's message across to a broader market. Instead of marketing directly to one large group of consumers, you pay influencers instead to get your message across. Besides, Hootsuite describes influencer marketing as a form of social media marketing that uses endorsements and product mentions from influencers - individuals with a dedicated social media following and are seen as experts in their field to promote products and services.

There are different definitions, but they have the common meaning that influencer marketing is a way for brands to leverage the power of social media and the influence of individuals with large followings to promote their products or services to a wide audience. In influencer marketing, influencers are typically compensated for their promotion of a product or service, either through payment or through receiving free products or services. Influencer marketing can be an effective way for brands to reach new audiences and build trust with consumers, as influencers are often seen as trusted sources of information and recommendations. However, it is important for brands to carefully select influencers who align with their values and target audience, and to ensure that any sponsored content is clearly disclosed to consumers.

2.3. Influencer marketing in the field of tourism

Influencer marketing has become increasingly important in the field of tourism, as more travelers turn to social media to research destinations and make travel plans. According to Bokunewicz (2017), in the context of global competition, influencers will help to attract more people, as they normally have many engaged followers, and easily to reach demographic targeted segments such as women. In addition, influencer marketing can improve and enhance the tourist destination, as a result creating a critical part of destinations' branding strategy (Gretz, 2018).

The rise of influencer marketing as a cost effective and high expansion results tactic of marketing has created new types of influencers in the tourism sector, such as Instagram travel influencers. Basically, influencers will provide real experienced recommendations more trustworthy than traditional advertising. This can help potential travelers feel more confident in their decision to visit a particular destination or use a specific. Influencers will provide real-experienced recommendations for tourists. Travel influencers often share their honest opinions and experiences, making their recommendations more trustworthy than traditional advertising. This can help potential travelers feel more confident in their decision to visit a particular destination or use a specific service.

Besides, influencer marketing also helps to build awareness and interest in travel destinations. By partnering with influencers who have a large following in the travel space, the travel destinations will be more famous and attract more tourists to visit. Influencer marketing will also drive bookings. By including links to tourism websites or booking platforms in their content, influencers can help drive bookings and increase revenue for tourism brands. Additionally, Influencer marketing helps to measure success. Its campaigns can be measured through metrics such as engagement, reach, and conversions, providing tourism brands with valuable data to inform future marketing strategies.

Therefore, influencer marketing can be a powerful tool for tourism actors who are looking to reach new audiences, build trust with potential travelers, and drive bookings.

3. Method

With the aim of understanding the current situation of influencer marketing in Vietnam, the study identifies systematic literature survey to gather information. It is clarified in Figure 1 as below:

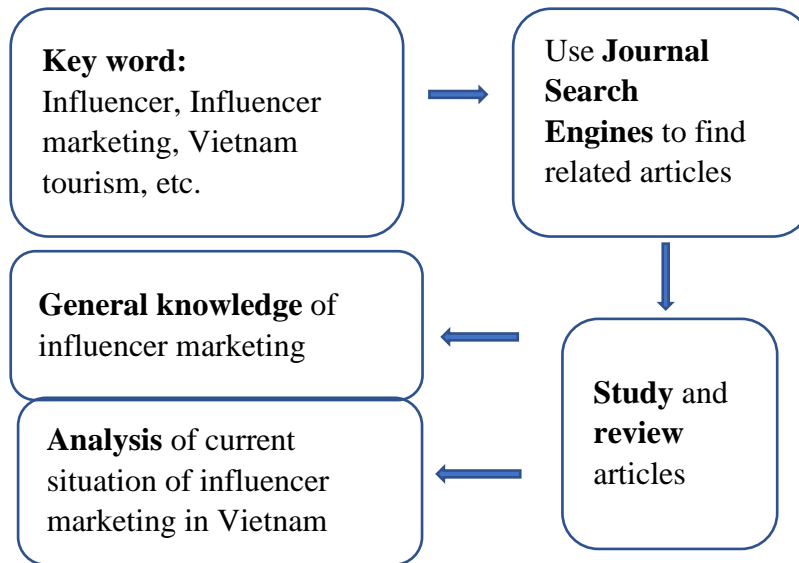

Figure 1. Literature survey process

4. Results

Influencer marketing is a rapidly growing and evolving industry in Vietnam, with both opportunities and challenges for brands and influencers. According to “The State of Influence in Asia 22/23” Report of Anymind Group, Vietnam is one of Southeast Asia’s most dynamic and fastest-growing markets for social media influencer marketing. With a population around 100 million people, there are over 145 million mobile phone connections (150% population penetration rate), with 68.17 million people (70% of total population) connected to the internet, and 65 million people on social media (67% of total population). Facebook is a platform dedicated to influencer marketing campaigns, with more than a quarter of all campaigns (79.1%) being conducted on the platform, followed by Instagram (9.8%), TikTok (7%) and YouTube (4.2%). TikTok is the most mentioned brand by Instagram influencers in Vietnam and it is also the only market where the platform leads in search. Following TikTok are two e-commerce platforms Shopee and Lazada, showing the market's interest in online commerce. In addition, no domestic brands appear on this list and 70% of the brands mentioned by influencers in Vietnam are Japanese and Korean brands. Based on another report from AJ Marketing, Influencer marketing in Vietnam skyrocketed especially by 26.4% in 2022. That's a staggering \$13 million increase from the previous year, pushing the total size of Vietnam influencer marketing in 2022 to reach \$64.23 million USD, including the money spent on online advertising activities such as posting on social media channels, published newspapers, etc. Vietnamese influencers have an abundance of opportunities to connect with their audience. Nearly a quarter (23.7%) of Vietnam's internet users follow influencers or experts on social media, spending a whopping 2 hours and 32 minutes each day scrolling through their feeds. 77% of them have been influenced to buy a product endorsed by an influencer. Additionally, Vero Asean's report said that 78% of businesses have spent a large amount of money on influencer marketing through advertising campaigns and it is expected to continue to increase for at least 2 more years.

As can be seen, in recent years more brands has recognizing the potential of working with influencers to reach Vietnamese consumers on social media. Influencer marketing has become one of the fastest-growing marketing strategies in Vietnam, as more brands shift their marketing budgets towards social media and influencers. Micro-influencers, who have smaller followers but high engagement rates, are becoming increasingly popular in Vietnam, as brands seek to reach niche audiences and increase authenticity. Vietnamese influencers tend to create content that is tailored to local audiences and culture, which can be especially effective in reaching Vietnamese consumers. The Vietnamese government has also recently introduced new regulations for social media and influencer marketing, requiring influencers to disclose sponsored content and imposing fines for violations. According to the Search Engine Journal's statistics on the objects and geographical territories of social networks, the highest percentage of social network users comes from the Millennials. Because they account for 32% of the world's population and 35% of the population of Vietnam, this generation is and will be the key generation in the global workforce, and also the main consumer that many brands are targeting. Especially, in the next few years, Millennials will become the main consumers in the travel industry, because they love to travel more than older generations. While Baby Boomers prioritize buying high-value items like homes and cars, Millennials tend to spend money on experiences, so Millennials are people who will spend on traveling at the highest level. In addition, when compared with other generations, Millennials use a variety of online information sources in travel decision making, because travel is a social experience of browsing information, decision making, purchase and post-purchase behavior (Schiopu, 2016). These factors are the main reason why travel influencer marketing is growing so fast recently. Influencer marketing will be one of the main strategies for tourism to develop. It is becoming increasingly clear that influencer marketing will greatly benefit the tourism industry. The emergence of influencer marketing not only energizes and dynamics the domestic travel market, but also helps brands connect with potential foreign markets. Travel advertising via influencer marketing just started around a few years ago, but now it has already become a big industry. Travel influencers are people who love to travel, experience exploring all over the world. They have high followers for certain audiences who are adventurous and passionate about discovery. Through posts shared on social networks, they will present and evaluate tourist attractions from their point of view and get the support and trust of the followers. Most users trust influencers more than ordinary advertisers or celebrities, therefore, the use of influencers in marketing strategies for businesses is extremely important. Not only does it help improve brand awareness, but it also returns a higher conversion rate than other communication methods.

Travel influencers have been a popular concept in recent years among young people in Vietnam, inspiring millions of young people to travel around the country and the world. They have many different ways to create online travel content according to their strengths and interests in that field, such as famous technologists, travel experts, people with deep experience in food or people with strong knowledge of fashion. In Vietnam, with the purpose of stimulating tourism, many localities have cooperated with leading influencers such as Khoai Lang Thang, Hoang Anh, Tran Thai Linh... This tourism trend has made many places

like Phu Quoc, Da Lat always in the top of the hottest tourist destinations in the list of travel agencies. Otherwise, some travel attractions are promoted by celebrities who are also famous people and have great influence on the public. Celebrities are often chosen to be the face of the brand, the brand's image ambassador such as actors, singers, television MCs...however there are also famous people who are influential in the tourism industry such as singer Quang Vinh, model Quang Dai, actress Diem My... Along with them, reputable people with extensive knowledge of different fields like fashionista, yoga teachers, travel bloggers, journalists, reporters...are also travel influencers, for example hot travel bloggers Le Ha Truc, Chan La Ca... Other influencers are ordinary people who have high followers and interactions on social networks like hotmom, entertainment vlogger...

Overall, influencer marketing in Vietnam currently develops fast and is expected to continue to grow in the coming years. However, this activity still faces different threats. For example, marketers are unclear of knowing how to connect with Influencers because they still largely depend on personal relationships, with no automated process. Or travel agencies have not invested enough time to manage multiple influencers for advertising campaigns, and they also lack a budget for the size of the campaign, leading to bad profit. Additionally, some local firms also do not have experience of working with influencers and as a result businesses will lose a lot of money, time and are not as effective as expected. There is also no particular system to measure the effectiveness of each advertising campaign corresponding to each influencer. So, travel firms cannot determine which source of profit depends on which group of influencers, it will be wasteful.

5. Discussion and Conclusion

5.1. Discussion

Influencer marketing in Vietnam tourism is getting great opportunities when it has a huge quantity of young effective influencers with many creative ideas, but this activity needs to be built into a long-term strategy. Based on analyzing the current situation, there are some proposed recommendations as follows.

Firstly, the Government and Ministry of Culture, Sports and Tourism need to continue to set up, amend and supplement the legal system and policies related to influencer activities to improve its efficiency. And travel companies or influencers need to follow updated regulations concerning influencer marketing in Vietnam to ensure that the campaigns are compliant and avoid any potential fines or penalties.

Secondly, the travel agencies need to develop clear strategies. They have to define the goals, target audience, messaging, and work with influencers to create content that aligns with their strategies. They also should have suitable measurements for success of influencer marketing campaigns and predict apparent future marketing performances.

Thirdly, travel locals also need to identify the right influencers to work with, carefully consider their niche, audience, and engagement rates. They should look for influencers who have a genuine interest in travel and who create content that aligns with your brand values and target audience.

Fourthly, the travel brands should collaborate with local tourism authorities who can help them reach a wider audience and access to destination-specific resources and expertise.

Last but not least, both travel agencies and influencers should focus on creating real content that showcases local culture and experiences and avoid content that feels overly promotional.

By following these recommendations, it is hoped that tourism brands in Vietnam can effectively leverage influencer marketing to reach and engage with travelers on social media, build trust and credibility, and drive bookings and revenue.

5.2. Conclusion

The explosive industrial revolution 4.0 has led to a shift to digital marketing strategies in promoting tourism, where influencer marketing plays an important role and is considered as one of the most effective ways to support travel brands and tourist destinations. Influencer marketing not only helps increase travel enterprise profits, promoting tourist attractions but also contributing to the development of Vietnam tourism. Despite some difficulties, Vietnam is one of the countries with many favorable conditions to develop this activity. In the coming time, influencer marketing will be one of the most popular strategies for tourism marketing campaigns in Vietnam.

DUAL PANEL MODEL OF CORPORATE GOVERNANCE AND FIRM PERFORMANCE IN PUBLICLY HELD ENTERPRISES

Dao Anh Tuan

Abstract

Although the corporate governance of publicly held enterprises today have changed drastically over the last 40 years, the businesses have remained under on-going threats of management failures and corporate financial scandals. This paper attempts to search for a new corporate governance system to accelerate the long-term performance of publicly held enterprises. We challenge the most prevalent assumptions about the public companies: Who is the owner of the firm? and what is really objectives of the modern firm? Based on historical and theoretical framework, we argue that neither shareholders nor stakeholders are the best “firm’s controllers”. Rather, we realize the role of the “firm-specialized investors” as key actors in our corporate governance model. After re-defining the firm’s objective and the firm’s owners (or controllers), we develop an original corporate governance model. In particular, we introduce an independent arbitration panel which is separated from management panel to form a dual panels system. The Dual panel model of corporate governance is expected to (1) eliminate the agency problem by an integration between ownership and management in management panel and (2) enhance team work and firm-specific investment by interest protection for the specific investors which is done by the internal court or Arbitration panel.

Our empirical results are robust to endogeneity concern. We found empirical evidence supporting the benefits of the Dual panel model of corporate governance to both market and accounting base measure of firm performance (Tobin’s Q and ROA). However, when we examine the relationship between our model and Economic profit (or Economic Value Added -EVA), no significant effect was found. A further exploration of the Dual panel model’s impact on EVA revealed the role of Arbitration panel in a corporate governance model. Especially, the incomplete independence of the panel might cause devastating damages for long term performance of publicly held enterprises.

Keywords: *Corporate governance; German firms; organization structure; Dual panel model*

1. Introduction

The Global Finance Crisis has unveiled a critical reason for the serial debacles of many giant companies worldwide during 2008-2009. That is a weak corporate governance

of publicly held enterprises where unaccountable auditors, faulty information disclosure, and misleading incentives can be found (Clarke, 2005, Gordon, 2002, Coffee, 2003-2004). The lessons from the collapse of Enron, WorldCom, Tyco, etc. have induced the enforcement of stricter controls on management (Samontaray, 2010, Shil, 2008, Wu, 2005). However, no matter how effective a control mechanism is acclaimed by theory, empirical studies have been unable to produce consistent conclusions about its performance (Adams et al., 2010). It reveals the fact that focusing on the control mechanisms for shareholders' interests alone maybe not be enough to improve the overall quality of corporate governance. Indeed, as the discussion by (Schmidt, 2004), instruments available for the stakeholders to exercise their rights are only one of the factors determining the characteristics of a corporate governance system. Other equally important elements include which stakeholder groups control power over the key decisions of the company, and how effectively they use the instruments. Although today's economics and finance textbooks follow the Nobel-prize-winning essay by Milton Friedman (1970) to describe shareholders as the only firm's "principals" and ultimate owners, historical evidence suggests that this is not always the case.

Indeed, from a historical perspective, the overproduction in the 1890s provoked "the Great Tycoons" to set up vertical integration which aimed at substituting uncertain market transactions with an under-control system using internal management bureaucracies. However, the success of internalization is conditional upon the existence of an internal decision-making structure where an effective group of managers is able to take over the functions that were formerly conducted by price and market mechanisms. When the form of business rapidly grew by dispersing their stock ownership during the 1920s, it also started to plant a seed of management disaster. The Great Depression in October 1929 which created unprecedented catastrophic consequences has raised serious questions about the role of modern enterprises. While the Populists believed that "big is bad" and the complex structure of organization makes it impossible to manage and control, Berle and Means (1932) argued that modern corporations were not the bottom line causing the Great Depression. The form of business still works as a remarkably effective engine, the problem lies in the remnants of the Great Tycoons' control which he believed totally useless, destructive, and appendage.

The historical lesson inspires us to challenge shareholder primacy after the Global Financial Crisis (Stout, 2012). Thus, it is high time we implemented an extensive search for a member who is greater knowledge about the business, is more reliable to stakeholders, and has stronger motivation in running the firm toward long-term development. The changes in the fundamental framework of modern firms induce a need for an innovative structure of corporate governance that can enhance teamwork in management, minimize agency problems, and encourage firm-specific investment should be recommended.

Our paper adds to the existing body of corporate governance area by proposing an original model of corporate governance which can enable publicly held enterprises to facilitate the firms' long-term development. The innovation of this paper lies in the original design of the corporate governance structure which is operated on the basis of two separate panels: the management panel which is run by highly motivated firm owners and the arbitration panel which works as an independent internal court.

The study is organized as follows: Section 2 will review the existing models of corporate governance. After evaluating the strength and weaknesses of each model, we will propose the Dual panel model of corporate governance in Section 3. The explanation for the method and empirical analysis of the relationship between the Dual panel model and long-term firm performance will be provided in Sections 4 and 5.

2. Literature review and theoretical framework

2.1. Literature review

An initial question that has bombarded economists is: Why do firms exist? Put differently, for organizing transactions, what factors shift market mechanisms to the internal arrangement? After Roald Coase published the book “The Nature of the Firm” in 1937 (Coase, 1937), the issue renewed scholars’ attention. Since then, the literature on this topic has evolved into three main streamlines of organizing economic activities including property right analysis, principal-agent analysis, and team production analysis.

From a contractual perspective, firms are established as a solution for dealing with transactional difficulties resulting from the uncertainty of long-term production relationships. Under this circumstance, designing complete contracts can be too expensive or impossible. The high degree of uncertainty makes contracting parties find difficulties in negotiation over who does what and who gets what. Consequently, it discourages them from maintaining the contractual relationship. In an attempt to fix this problem, the property rights analysis suggests a mechanism in which interest conflicts can be cleared up through a specific allocation of property rights. In particular, explicit contracts can be substituted by cooperation in which property rights are transferred to one of the involved parties who contributes critical inputs to the joint production.

Building on this view, the conventional model of corporate governance focuses on the relationship between principals and agents in which productive relationships within a firm are organized into a vertical hierarchy (See Figure 1). At the top of the pyramid is the principal who is seen as the ultimate owner of the firm’s assets. The owner transfers their authority over the assets to agents who are practically in charge of running the business.

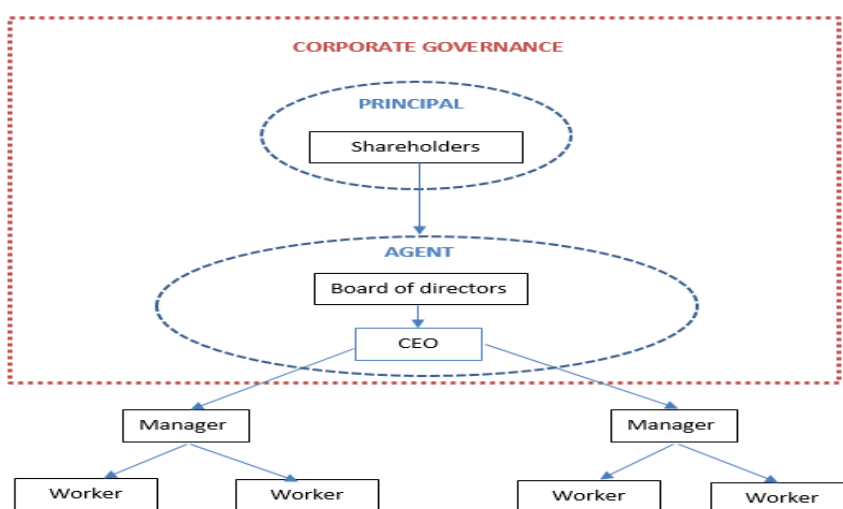

Figure 1. Conventional model of corporate governance

The conventional model has been criticized for its assumption of a clear definition of principle. In publicly held enterprises, critical inputs for joint production are provided by a group of people which ignites a major dilemma in devising incentives to overcome the free-riding and rent-seeking of team members (Alchian and Demsetz, 1972). The suboptimal outcomes, which result from self-interest motivations in team production, induce a viable solution adopted by Alchian and Demsetz (See Figure 2). In their suggested system, one member will step aside and perform a role of a monitor who keeps an eye on the rest of the team members' performance to detect and punish the selfish behaviors of the members. As a consequence, the monitor will have residual rights over the group return. Whereas, other team members turn into employees who received a fixed income. The system's benefits, therefore, are argued to be twofold. While it provides sufficient incentives for the monitor to police against shirking, the pre-determined wage for other team members can disable motivation for rent-seeking.

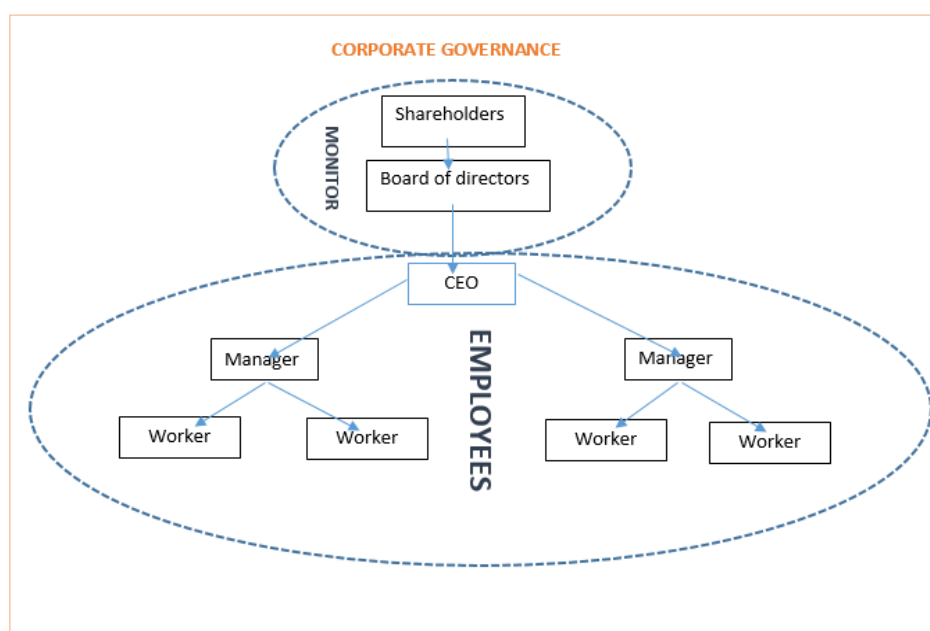

Figure 2. Monitor- employee model of corporate governance by Alchian and Demsetz

In this model, its assumption of uniform or interchangeable “employees or inputs” which can be hired on the market through explicit contracts is questioned by Bengt Holmstrom (1982) who proved that it is impossible to write such kind of contracts. “Holmstrom’s impossibility theorem” is especially true in case a firm needs specialized inputs which cannot easily find on the market.

According to Raghuram Rajan and Luigi Zingales (1998), a fundamental reason for the existence of joint production lies in the potential value from the aggregation of different specific-input providers. Undeniably, gains from team production projects are undertaken only if all members make some form of firm-specific investment. It can be succinctly explained by the fact that if all necessary firm-specific investment is put in the hand of a single member, there will be no motivation for him to enter a corporation with other members because he can simply hire interchangeable workers on the market which its prices and

quantities are explicitly pre-set like any other inputs. The only reason for him to invite others to join his project is that his partners can provide potential resources that he does not have and it is not easy to find on the market. Hence, the added value of new partners to the team production comes from their contribution of productive resources which are specific to the team’s needs.

In order to deal with the obstacles for firm-specific investors, Blair and Stout (1999) organize a corporate into several layers of hierarchy (See Figure 3). At the top layer is a board of directors who possess ultimate power over the corporate assets. This unit is formed by individuals who are representatives of team members and some outsiders. Members at lower layers can negotiate with their “direct boss” on his decisions that they are unhappy with. Generally, they will make the best efforts to arrive at a compromise by themselves or by the judgment of BOD. Otherwise, the dissenting members will either voluntarily leave or be forcefully removed from the corporation, as a result, lose their firm-specific investment or future rent.

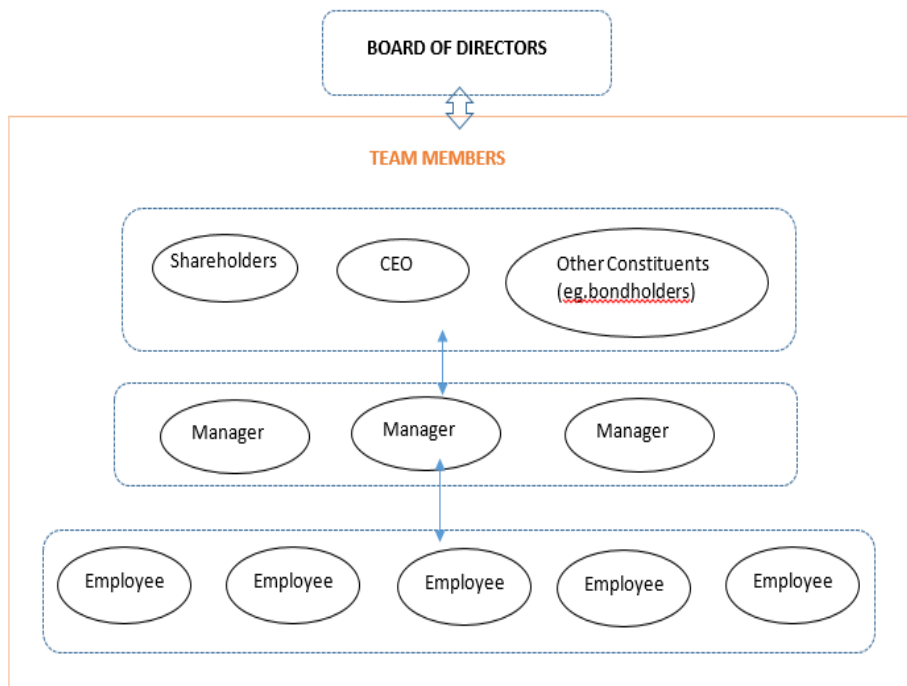

Figure 3. Mediating hierarchy model of corporate governance by Blair and Stout

In the mediating hierarchy model, Blair and Stout have added two more functions to the hierarchy. Besides the benefits to higher levels of hierarchy from boosting upward information flow and downward decision processes, the model also benefits horizontal relationships by overseeing shirking behaviors and conciliating disputes among team members. As a result, the last two functions have significant contributions to encouraging all members to make sufficient firm-specific investments. The introduction of mediating function to hierarchy implies that no team member takes the role of a principal because ultimate control rights over the team’s assets and outputs are transferred to an independent entity.

Dual panels model of corporate governance

After reviewing the existing models of corporate governance, we develop a dual panels system of governance which is formulated in line with radical revision in basic assumptions of public corporates. The ultimate aim of this model is to drive the managerial team to undertake long-term strategies that focus on value creation for the economy, their business, and inherently for themselves.

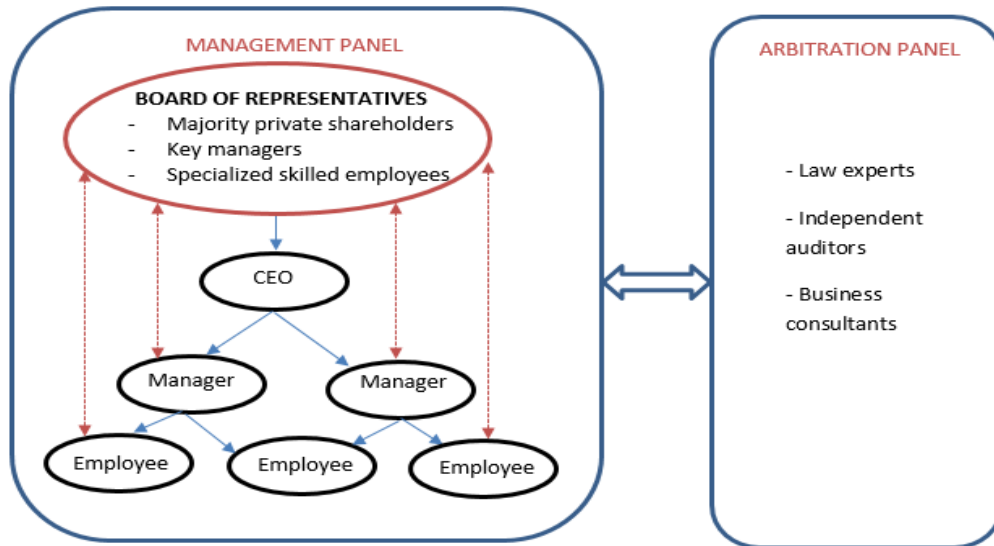

Figure 4. Dual panels of corporate governance

In order for the model to achieve the above objectives, we introduce an independent arbitration panel which is separated from the management panel to form a dual panels system (See Figure 4). The management panel is organized as a vertical hierarchy. At the top of the panel is the Board of Representatives who take ultimate control over the firm's decisions and receive residual income. The distinctive feature of the Board of Representatives (BoR) is that all of its members are composed of the firm's long-term owners who have a long-term stake in the firm. They are expected to exclusively work for a single objective of value creation because as a private company, the firm's owner has no choice but to make money and to create added value. In other words, BoR is treated as a single unit where, just like the private owner, the BoR's members are the key firm's owners who are also in charge of management.

Since we delegate control rights to firm-specific investors (as discussed in the previous part), BoR, in the dual model, is proposed to be composed by the control owners in order to fuel the management panel with strong motivation for seeking higher value. Indeed, the investment of the control owners is locked in the firm which makes their private interests align with the long-term interests of the firm, just like private owners in private companies. As a result, they are willing to run the business toward long-term objectives.

As control owners who provide key inputs to the production, BoR's members should be given property rights over the firm assets. It means that they possess two control rights over the firm: (1) control rights over the firm's decisions and (2) residual rights over the firm's outputs as suggested in the property rights theory. Regarding the control rights over

the firm's decisions, the BoR's members have the right in participating in making both operational and strategic decisions. Also, the BoR's members have the right to appoint a CEO who is one of the BoR's members to lead the board into cooperative decisions. The peculiar feature of the CEO is that she has limited power over the firm's decisions because all the decisions must be consulted with all the BoR's members. Indeed, as Galbraithian CEO, the most important role of the CEO is to coordinate and exploit his team members' knowledge to improve the overall efficiency of the firm's decisions that an individual working alone could not achieve. In this sense, the BoR is a powerful decision-making engine that includes all internal experts on managerial, and technical issues. A successful CEO, therefore, must exploit powerful resources to make valuable decisions for the business. As a result, the CEO has to actively consult with other BoR's members to run daily business operations in line with the technocracy's strategic goals.

2.2. Hypotheses and constructs

Besides investigating the overall effect of the Dual panel model, we develop five hypotheses which manifest the five typical characteristics of the model besides in order to test the effect of the Dual panel model on firm performance in more details. As mentioned in previous section, the five main features of the Dual panel model include (1) Incentive for management; (2) Interests alignment; (3) Mutual monitor; (4) Board performance; and (5) Independent arbitration panel.

2.2.1. Incentive for management and firm performance

In an agency relationship, the principal faces an information asymmetry problem which gives agents opportunities to reap private benefits from hidden action (or moral hazard) and hidden information (or private information) (Bohlin, 1997).

In the Dual panel model, management is encouraged to pursuit sustainable objectives rather than an investment myopia. We, thereby, expect an incentive scheme that depends mainly on pay for performance and long-term managers' tenure to attach the management's interests to the enterprise's long-term strategies.

Hypothesis 1: Managerial incentives which emphasize on pay for performance and long-term interests' attachment to the firm will improve the firm performance in the long run.

2.2.2. Interest alignment and firm performance

The managerial ownership can benefit the firm performance because as their stake increases, managers bear a greater share of the cost of interest's deviation. They, therefore, are more likely to act in shareholders' best interests. The standpoint is known as the "convergence of interest hypothesis" which suggests that insider ownership increase with market value. Stulz (1988) revealed an advantage of increasing the shares owned by managers which can protect the company from a hostile takeover. He argued that the chance of successful takeover bids is substantially lessened as the managerial ownership increase. Even, the probability of success would reduce to zero when managers' ownership reaches a 50% fraction of equity. Similarly, Weston (1979) also found that there were no attempts to take over the firm with over 30% insider ownership.

The Dual panel model aligns the different interests of stakeholders through the integration of management and ownership. In particular, we suggest that the firm-specific investors, who provide key inputs to the firm, are also responsible for managing the business. In this case, the firm's owners also engage in both managing and directing the business. The interests of managers and owners, therefore, are converged.

Hypothesis 2: The closer interests and relationship between manager and owners a firm has, the higher firm value they make in the long run.

2.2.3. Mutual monitor and firm performance

In a corporation, although the CEO plays a central part in the decision-making process, management of the enterprise requires extensive efforts via teamwork. Thus, promoting mutual monitoring within the management team can effectively control unethical, self-serving, and absenteeism behavior in top managers. As a result, CEOs who seek for "quiet life" will be easily noticeable and removed by other managers. The more active and capable CEOs are, the more willing they undertake potential projects with high returns (Dominguez-Martinez et al., 2008, Hermalin and Weisbach, 1998). We, therefore, expect that mutual monitoring within the management team can benefit a firm performance.

Hypothesis 3: Under a gain-sharing incentive scheme, mutual monitoring within board management can boost a firm performance by curbing its CEO from empire-building and seeking a 'quiet life'.

2.2.4. Board performance and firm performance

In the Dual panel model, the Board of Representatives (BoR) plays a central role in the management panel. Like Supervisory Board, the BoR is suggested to fulfill two major roles: overseeing CEOs and setting strategy. Although a board is, in theory, expected to successfully fulfill its duties when it is composed of highly qualified members, the board may not function properly if its directors are negligible to their job. Empirical evidence shows that boards tend to be passive when exercising control and disciplining their CEOs (Lorsch and Young, 1990); statistics of Demb and Neubauer (1993) indicate less than a quarter of directors agree that they serve as watchdogs for shareholders. The board's functions, therefore, can be effectively carried out only if directors are active to engage in the board's activities. The board performance, accordingly, can be judged by the board size, meeting, and board attendance.

From an organizational perspective, larger boards can lead to cooperation difficulties which can be harmful to the board's effectiveness. As the size increases, the board's decisions are likely to be harder to reach and the board's productivity can be hurt due to the emergence of free-riding and cooperation problems. Some empirical evidence of an inverse association between board size and firm value can be found in a sample of the large US firm (Yermack, 1996), and smaller Finnish firms (Eisenberg et al., 1998).

In the Dual panel model, the board plays a crucial role in overseeing and advising CEO. They are, therefore, expected to be active and closely work with the CEO.

Hypothesis 4: The more active efforts of directors dedicated to a board, the more effective the board work to monitor the CEO's performance. As a result, it can improve the firm performance.

2.2.5. Arbitration panel and firm performance

It is expected that the higher quality the board committees can enhance the board monitor over the management, and alleviate agency problems, resulting in greater firm performance (e.g., (Carcello and Neal, 2000, Carcello and Neal, 2003, Andres and Vallelado, 2008, Ahn and Choi, 2009, Morey et al., 2009). For instance, the compensation committee is designed to develop, advise, administer, and oversee executive compensation schemes. The better performance of the compensation committee, therefore, can establish and implement more effective compensation plans which align the interests of different stakeholders and motivate management to make preferable decisions. The audit committee is responsible for the disclosure of accounting information. Their competency will ensure stakeholders obtain reliable, relevant information in a timely manner. Thus, it provides efficient control monitor on management, leading to fewer failures in firm performance. Similarly, the role of the nomination committee is interpreted to be director selection and board appointments. It determines the quality of directors appointed to the board and, therefore, affects the board's performance.

Hypothesis 5: The more objective the Arbitration panel is, the more interests of the firm-specific investors are better protected. Investors have more incentive to make sufficient investments for the firm-specific needs which can enhance the firm performance.

3. Method

3.1. Corporate governance index

3.1.1. Developing CG index (Dual_Score)

For the purpose of exploring the effectiveness of the Dual panel model, we developed a corporate governance index based on five distinctive features of the Dual panel model. Specifically, five correspondent sub-indices has been employed to represent these distinguished characteristics of our model of corporate governance including: (1) Incentives for long term objective; (2) Interests alignment between owners and managers; (3) Self-monitoring within management team; (4) Board performance; and (5) Independent justification for internal relationships and conflicts (which I use the independency of firm's committees as a proxy).

3.1.2. Measurement Corporate governance index

We rely on 33 individual governance attributes to construct five sub-indices of corporate governance. In order to quantify these attributes, we give a score to each attribute on five scale basis (from zero to four). In principle, a firm will be rated according to its compliance with recommended practices by the Dual panel model. Specifically, we use the same approach as Aggarwal et al. (2009) who assign the highest score (four points) to a firm that has recommended CG attributes in place, and the lowest score is given to a firm if we

cannot find the evidence for its implementation of the model's suggestions. In case of missing data, the firm will be penalized by getting zero points. The score not only implies that we treat the firm as if it had not adopted the recommended corporate governance but also evidently indicates the failure of its corporate governance when the firm handicaps its public owners' power by deliberately or unintentionally failing to disclose relevant information.

After recording the score, total points rewarded to a sub-index will be computed by adding up scores of all attributes under the same category. The earned points are then, divided by the maximum score a firm can get, that is, multiplying four points by the number of attributes in the sub-index. The result produces a relative number (percentage) that indicates the level of a firm's CG adoption in relation to the benchmark suggested by the Dual panel model. Finally, we take the average of all five sub-indices to produce the DUAL_SCORE for each firm.

3.2. Firm performance

Among market-related indicators, Tobin's Q is the most outstanding proxy for firm performance due to its advantage in anticipating the impact of corporate governance structure on current and future firm performance. However, Bhagat and Jefferis (2002) provide strong evidence that the relationship is more spurious than causal. In particular, the denominator of Tobin's Q tends to exclude the firm's investment in intangible assets. At the same time, firms which are made up of a majority of intangible assets are more likely to have a greater level of managerial ownership. This is because when it is difficult for shareholders to monitor intangible assets, the firm can stimulate interest alignment by providing managers with the firm's ownership. As a result, firms with higher levels of intangible assets or higher Tobin's Q (due to a smaller denominator) tend to have greater ownership by managers. In this case, the positive correlation between firm performance and the aspect of corporate governance, therefore, is not casual. Another claim for the spurious relationship argues that while market power might positively affect Tobin's Q, the firm's power also protects managers from the market's disciplines. The lack of control over the managers pushes shareholders to share their ownership with the managers. In this case, we would again expect a spurious relation between Tobin's Q and corporate governance.

3.3. Data collection method

We try to acquire a representative sample to equip our findings with external validity and allow generalization. Specifically, we use a simple random sampling method to collect data. To obtain a simple random sample, we, first, define our sample frame which is German firms listed on the Frankfurt stock market (CDAX). As of 2019, there are more than 500 companies listed on the stock market. Each of these companies, then, is assigned to a specific number. Finally, we use the random function in Excel ("RANDBETWEEN (1, 500) to choose companies with the corresponding number produced by the Excel. The chosen firms will be used to construct our sample.

More specifically, we, first, start with a preliminary sample of 250 firms over six-year period from 2017 to 2019. Our choice of this time frame aims to obtain a sample of

listed companies characterized by the most variation in their corporate governance practices as a consequence of the 2007 global financial crisis. As a result, it can make the interpretation of statistical results on the relationship between corporate governance and firm performance more meaningful.

For each firm, we collect 33 attributes of corporate governance every year. After obtaining the data, we decided to exclude from our analysis 175 firms due to their missing information on one or more attributes of corporate governance. This yields a sample of 75 firms having completed data on corporate governance for the above six-year period. We, then, acquire data on control variables and take logarithms for all variables which further eliminate 35 firms for their lack of information. The remaining 40 firms, which is equivalent to 240 observations, make up our preliminary sample used in our analysis.

4. Results

4.1. Overview of the sample

We use firm-level data provided by Bloomberg to acquire our sample. It comprises 40 listed companies from all sectors classified by GICS for a six-year period. As can be seen in.

Table 1. Summarize of observations by Sectors and by Firm Size.

PANEL A: SECTOR	Freq.	Percent	Cum.
Communications	6	2.5	2.5
Consumer Discretionary	42	17.5	20
Consumer Staples	12	5	25
Energy	6	2.5	27.5
Health Care	30	12.5	40
Industrials	60	25	65
Materials	54	22.5	87.5
Technology	18	7.5	95
Utilities	12	5	100
Total	240	100	

4.2. Multivariate analysis

For empirical analysis, we use fixed effects regression for lagged, transformed variables and with standard errors that are clustered at the firm level. The regression investigates the relationship between corporate governance and firm performance based on a number of alternative setups.

We, first, examine the overall effect of the Dual panel model of corporate governance on different measures of firm performance including Economic profit (EVA), Tobin's Q and Return on assets (ROA). Table 2 shows the statistical results for the three models which

reveal two main following points. In the first place, all models yielded identical results about the effect of capital intensity on the firm performance. Specifically, the Capital intensity negatively correlated with all performance measures such as EVA, Tobin'sQ and ROA. This result is acceptable for our sample which covers the period of the global financial crisis. The economic turmoil posed extra business risk to German firms. As a consequence, the high density of capital generated financial burden on the business and harmed the firm performance.

The second point, which is also the most important feature to note, is that the statistical results found consistent but not solid evidence supporting the role of Dual panel model of corporate for promoting firm performance. As can be seen in the Table 2, although all models consistently produce positive coefficients of the DUAL_SCORE which empirically prove the benefit of the Dual panel model to German firms, significant effects were only seen in Model 2 and 3. In particular, while the Dual panel model significantly improve the firm performance measured by TOBIN'sQ and ROA at 5% and 1% significant level, we cannot find a similar extent of effect on Economic profit (EVA).

Table 2. Corporate governance and firm performance

Moreover, the Model 1, which focuses on the relationship between Dual_Score and Economic profit, is also the least efficient model in comparison with the last two models. In particular, the Model 1 gains the lowest within-R² as well as the Rho's value, only 0.0882 and 88% respectively. We, therefore, tried to improve the model by a further exploration of

the Dual panel model's impact on EVA in the next model. The Model 4 was conducted by decomposing the DUAL_SCORE into five sub-categorizes which represent distinguished characteristics of the Dual panel model including: (1) Incentives for long term objective; (2) Interests alignment between owners and managers; (3) Mutual-monitoring within management team; (4) Board performance; and (5) Arbitration panel. In the Model 4, we also introduce interaction term to examine how the sub-indices substitute or compliment to each other. The model's result is shown in Table 3.

Table 3. Sub-indices of Dual panel model and firm performance

More importantly, the Arbitration panel variable has the largest absolute effect size on EVA which indicate the fact that the Arbitration panel, in the Dual panel model, plays a key role in determining the long-term performance of publicly held enterprises. Adding to this point, the negative link between the independence level of “board committees” and EVA due to the lack of perfect independent committees in German firms confirms a central idea of the Dual panel model. That is to set up a structure of corporate governance that separates management from a perfectly independent monitoring panel that is able to provide objective judgment on any disputes and conflicts among members of the Board of Representatives. We can argue that if the shareholders need to monitor their management team to protect their self-interests, the managers also want to check on shareholders' behavior before contributing

their efforts because this human capital is the firm-specific investment that can be taken by shareholders. In this situation, the independent Arbitration panel must protect the interests of all parties, instead of one or some particular groups of stakeholders. To sum up, although our model cannot explicitly prove the positive effect of the Arbitration panel on EVA the findings reveal that the Arbitration panel which gives a group of stakeholders the advantage of control power is a pivotal component in a corporate governance model and the less independence of the panel might cause devastating damages for the long term performance of publicly held enterprises.

Finally, Model 4 also revealed the inter-relationship among the sub-indices of the DUAL_SCORE. The significant effect of the interaction terms between Interest alignment and Mutual monitoring means that what is the effect of Interest alignment mechanisms on EVA will depend on the level of Mutual monitoring within the management board. The positive value for the coefficient of the interaction term would imply that the stronger the mutual monitor exercised on the management board, the greater effect of mechanisms for Interest alignment on EVA. In other words, the two indices complement to each other and our model which is designed with the co-existence of the two mechanisms can boost Economic profit growth more rapidly.

5. Conclusion

Our empirical results provide support for the claim that public companies can gain great benefits from the Dual panel model. The finding is strongly corroborated by robustness tests which show the significant positive impact of the model on both market and accounting-based measurement of firm performance (Tobin's Q and ROA). However, EVA, a more recently developed indicator that financial experts believe to be a guideline for firms' long-term performance, unexpectedly has no association with the Dual panel model. It raises a tricky question as to the effectiveness of the model in the long run

In an attempt to explain the odd result, further exploration of the Dual panel model has revealed an interesting implication for practice. By decomposing the DUAL_SCORE into five sub-categories which represent typical features of the Dual panel model, we find that all the corporate governance features confirm our hypothesis on its impact on the firm performance except for the last characteristic of the Arbitration panel. In particular, mechanisms for Interest alignment, Mutual monitoring, and Board performance significantly improve the Economic profit, but mechanisms for the Arbitration panel surprisingly obstruct the firm performance. An explanation for the unusual result, however, provides us with an important conclusion. The lack of perfect independent committees in the Arbitration panel in German firms may cause a negative impact on EVA. This empirical evidence accentuates an important feature of the Dual panel model which tries to separate management from a perfectly independent monitoring panel that is able to provide objective judgment on any disputes and conflicts among members of the Board of Representatives. Any Arbitration panels which are influenced by a group of stakeholders might cause devastating damages to the long-term performance of publicly held enterprises.

Abstract

Environmental issues, especially domestic waste (DMW), are always one of the most notable concerns of every country in the world, including Vietnam. The article refers to the current situation of garbage classification of people in the city of Hanoi; thereby analyzing and evaluating the factors affecting the decision to classify domestic waste of people. The study was conducted from the survey results of 349 valid questionnaires from people living in Hanoi. By using regression analysis, Cronbach's Alpha test, exploratory factor analysis, the research paper identifies the factors affecting the classification of household waste in Hanoi city including: (1) Attitudes, (2) Subjective Standards, (3) Perception, (4) Expectations, (5) Legal system, (6) Propaganda activities, (7) Knowledge. From the research results obtained, the article proposes some solutions to improve people's awareness in building the habitual practice of classifying domestic waste at source, thereby contributing to great benefits in improving the quality of life of the people accommodating in Hanoi city in particular and the surrounding environment in general.

Keywords: *Classification of domestic waste, Domestic waste, Hanoi people.*

1. Introduction

Domestic waste (DMW) has always been an extremely chronic problem for every country in the world, requiring governments to take the right measures to handle the huge

amount of waste that is multiplying every day. World Bank's statistics (The World Bank, 2018) indicate that every year, 2.24 billion tons of municipal solid waste are generated, with at least 33% not being managed in an environmentally secure way. With this situation, it is extremely necessary and urgent to execute in-depth research on waste as well as measures to classify domestic waste in order to reduce and treat waste thoroughly.

In the United Kingdom in 2016, authors Ebikapade Amasuomo & Jim Baird of Glasgow Caledonian University, UK conducted a research project on "The definition of waste and waste management" to provide answers to 3 questions: What exactly constitutes waste? How much do we know about what should be classified as waste? What is the historical background of waste management? From their research, the authors have come up with the most basic definition of waste through previous studies, the context of foundation and development of waste management as well as 3 waste classifications based on: condition, origin and level of impact on the environment. Through this, the authors have suggested that the government should take pre-planned measures to thoroughly deal with the amount of waste in the future. On the other hand, in China, the study of two authors Baiqiang Gan, Chi Zhang (2006) through interviews and questionnaire surveys in Guangzhou to collect sample data, thereby obtaining the influence levels of residents' attitudes towards garbage sorting, subjective norms, perceived behavioral control and situational factors, and government legislation on residents' willingness to sort household waste. The results of the study showed that people's attitudes towards the segregation of household waste are very important and the government regulatory control factors are the main elements influencing the people's willingness to sort garbage.

In Vietnam, according to the National State of the Environment Report for the period 2016-2020, the volume of DMW discharged into the environment continued to increase across the country. It is estimated that the amount of waste generated in urban areas nationwide increases on average 10 - 16% annually. The amount of municipal solid waste has increased sharply in big cities such as Hanoi, Ho Chi Minh City, Da Nang, and Hai Phong. The total volume of domestic solid waste generated nationwide is about 64,658 tons/day, equivalent to 23.6 million tons/year. Particularly in Hanoi, the second largest city in Vietnam, up to 7000 tons of domestic solid waste is generated and needs to be treated every day. In order to solve this situation, scientists, environmental management agencies and policy makers in our country have been paying more attention and research to waste and waste classification and management. Le Ai Tam, Nguyen Thi Hong Nhung and Ho Huu Loc (2018) investigated the main factors that influence the intention and behavior of household waste disposal according to EFA (Exploratory Factor Analysis) method and TPB (The Theory of Planned Behavior) model. Initial results show that factors such as attitudes, social definitions and perceptions affect people's actual behavior, and attitudes strongly affect the level of waste classification of residents in District 8. Then in 2020, in order to expand the analysis scope of solid waste classification behavior, author Nguyen Thi Hong Hue and colleagues analyzed the factors affecting the decision to classify domestic solid waste as a source of the people in the northern provinces of Vietnam, thereby providing

practical suggestions and solutions to the government, the agencies, companies, environmental organizations and the people themselves. In addition, Decree 45//2022/ND-CP of the Government of the Socialist Republic of Vietnam on "Regulations on administrative violations in the field of environmental protection" implemented since August 25, 2022, has shown the State's special attention to waste management as well as making waste sorting at source a mandatory action for individuals and households.

In the capital city of Hanoi, which has the highest population density in Vietnam, every day up to 7,000 tons of domestic solid waste is discharged and needs to be treated every day. However, there are still many limitations in waste management, leading to the accumulation of waste and no treatment method, which seriously affects the landscape, environment and human health. Meanwhile, the method of waste treatment in almost all treatment sites is still mainly landfilling, not yet putting advanced technologies into treatment, such as technology to convert waste into energy, etc. Because of that, over time, the area used for landfilling is increasingly shrinking and the infrastructure is overloaded, leading to incidents. Such times make the collection and treatment of garbage interrupted, causing a backlog of garbage in the environment for many days. This situation has prompted the People's Committee of Hanoi City to immediately deploy the classification of domestic waste at source in order to reduce the amount of waste that needs to be treated every day. In fact, as soon as it is deployed, the movement of garbage sorting is gradually becoming animated, being executed with great enthusiasm by everyone. According to the report of the Department of Natural Resources and Environment of Dong Anh district, by the end of March 2022, in the district, there were 23 communes and towns participating in the program of collecting, sorting and treating garbage at home. However, the policy of classifying domestic waste is still facing many difficulties due to lack of facilities or because people's awareness has not yet been changed.

Therefore, based on practical requirements, the article conducts a study on factors affecting the classification of domestic waste of people living in Hanoi city. This study will detect and measure the factors affecting the decision to classify waste of people in Hanoi city as well as propose some recommendations and solutions to help the classification of waste become more accessible, thereby promoting people to actively participate in the classification of DMW.

2. Theoretical framework and Methodology

2.1. Theoretical framework

The study is based on the following three theories:

The Theory of Planned Behavior (TPB) was developed by Ajzen in 1985 with the inheritance and development from the Theory of Reasoned Action (TRA). During the research, Aizen (1991) found that behavioral intention will be constrained by the environment, so he added an influencing factor to the TPB model of planned behavior theory. Accordingly, the TPB behavioral theory suggests that there are three factors that affect behavior: Attitude (AT), Subjective norms (SN) and Perceived behavioral control (PBC) controls).

The Expectation Theory, put forward by Victor Vroom, a professor at the Yale School of Business Administration, shows that an individual's working motivation is influenced by their expectations of the results to be achieved and the attractiveness of the results to the individual. The Expectation Theory is an important theory on the process of recognizing human characteristics. The Expectation Theory assumes that the desired reward or outcome will be able to stimulate a person's behavior. Indirect experience, anticipation, and associations can in fact induce behavior, and it can also create associations between hope and outcomes. From there, applying the theory of expectation to the study shows the factors that constitute direct and indirect motivations for the formation of garbage sorting habits of people in Hanoi city.

Intrinsic Motivation, according to two psychologists Edward L. Deci and Richard M. Ryan, refers to the fact that actions are motivated by internal motivations, which are derived from the inherent satisfaction of the activity (*Intrinsic Motivation and Self-Determination in Human Behavior*, 1985). This motivation is determined by three essential, innate, psychological human needs that directly lead to behavioral motivation: autonomy, competence, and relevance (Ryan & Deci, 2000). In addition, intrinsic motivation is determined by conformity with personal values. Individuals can do this by achieving clarity around their values and identifying how activities promote and support them (Vansteenkiste et al., 2018). These factors all affect people's decision-making about garbage classification.

2.2. Hypothesis Development

Based on the background theory and previous research models, the study proposes a model of factors affecting the garbage classification behavior of people in Hanoi, including 7 factors: *Attitude towards garbage classification behavior (AT)*, *Subjective norm (SN)*, *Perceived behavioral control (PBC)*, *Expectations about garbage sorting behavior (EXP)*, *Legal and regulatory system (LS)*, *Propaganda activities (PA)*, *Knowledge of garbage classification (KN)*.

$$\text{WASTECLASSIFICATION} = \alpha + \beta_1\text{AT} + \beta_2\text{SN} + \beta_3\text{PBC} + \beta_4\text{EXP} + \beta_5\text{LS} \\ + \beta_6\text{PA} + \beta_7\text{KN}$$

In particular, the factors of the research model are explained as follows:

Hypothesis H1 - Attitude has a positive impact on the classification of garbage of people in Hanoi city

Attitude in the TPB theoretical model is defined as the positivity or negativity, satisfaction or dissatisfaction that an individual feel when performing a certain behavior. In the study of Best & Mayerl, 2013; Nixon & Saphores, 2007, attitude is defined as the perception of people's behavioral trends towards the classification of garbage. Therefore, if there is a positive attitude towards waste segregation, then people will have a greater intention to participate with a greater tendency to do so and vice versa.

Hypothesis H2 - Subjective norm has a positive impact on the classification of garbage of people in Hanoi city

Subjective social norms or subjective norms are often thought to control an individual's perception of being important to others in a social environment in which they desire or expect that person to behave in a certain way (Ajzen 1991). In this study, subjective social norms refer to the influence of external social pressures on people's willingness to sort garbage. The greater the social pressure people perceive about garbage segregation, the more willing they are to participate (Matthies, Selge, & Klöckner, 2012; Ru, Wang, & Yan, 2018).

Hypothesis H3 - Perceived behavioral control has a negative relationship with the garbage classification of people in Hanoi city

Perceived behavioral control (PBC) was defined by Ajzen (1991) as a type of belief held by a person about how easy or difficult it is to perform a behavior. An individual will think that the more resources and opportunities they possess, the fewer difficulties and obstacles they will have, and the greater their perceived control over behavior. Previous studies have demonstrated that the application of behavioral control does not predict intention in many cases (Eagly & Chaiken, 1993; Mcmillan & Conner, 2003). When putting perceived behavioral control into the research topic, the authors found that people tend to control their garbage sorting behavior based on barriers or factors that support garbage classification.

Hypothesis H4 - Expectations affect the garbage classification of people in Hanoi city

The individual's perception is reflected in overcoming barriers to performing a behavior. In addition, an earlier study (Kraft, P.; Rise, J.; Sutton, S.; Røysamb, E. *Perceived difficulty in the theory of planned behaviour: Perceived behavioral control or affective attitude? Brit. J. Soc. Psychol.* 2005, 44, 479-496) proposed that perceived behavioral control includes both intrinsic and extrinsic cognitive factors. Internal factors mainly refer to skills, knowledge, information identification and confidence, while external cognitive factors include time, energy, costs and other aspects. In this study, the internal factors of perceived behavioral control are equivalent to the expectation factors of the expectation theory.

Hypothesis H5 - The legal and regulatory system has a positive relationship with the garbage classification of people in Hanoi city

Noehammer and Byer (1997) argued that mandatory recycling programs introduced by the government have a higher participation rate than residents who voluntarily recycle. Yu, He, Li, Huang and Zhu (2014) demonstrated that the legal and regulatory system has a positive impact on people's willingness to classify solid waste. It proves that the legal system and government regulations play an important role in the classification of people's domestic solid waste.

Hypothesis H6 - Propaganda activities have a positive relationship with people's garbage classification in Hanoi city.

Previous research has shown that attitude towards the environment is a poor predictor of subsequent behavior (Costarelli and Colloca, 2004). It is clear that in order to change behavior, awareness must be enhanced (Gunton and Williams, 2007). Therefore, forms of

waste management need to be fully communicated to the public, by changing old habits for the better (Read, 1999, Gunton and Williams, 2007). Propaganda activities can also promote people's awareness of the importance of waste segregation, thereby encouraging people to do garbage sorting more actively.

Hypothesis H7 - Knowledge about garbage classification has a positive relationship with people's garbage classification in Hanoi city

Through previous studies, knowledge about garbage classification is divided into two categories (Zhang, Huang, Yin & Gong, 2015). The research focuses on general knowledge of the concept, usefulness of garbage classification and technologies for waste segregation (Fryxell & Lo, 2003). They are considered as one of the main drivers of garbage classification. Many articles have shown that there is a significant relationship between knowledge of garbage classification and garbage sorting behavior (Hansmann et al., 2006; Wang, Guo, & Wang, 2016).

Research model has been designed in Figure 1, below:

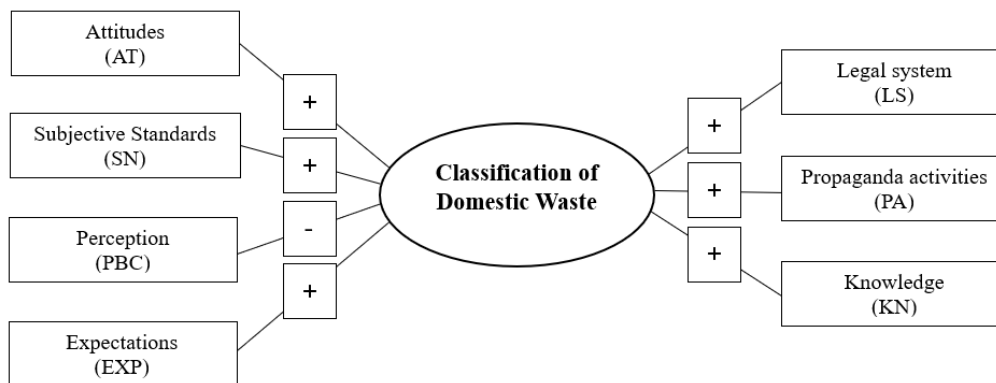

Figure 1. Proposed Model

Scale: Based on the background theories and previous studies related to the factors affecting the garbage classification, a number of factors and hypotheses have been selected, along with the current situation and problem of garbage classification of the people of Hanoi today, the article proposes a scale of influencing factors in the proposed research model before consulting experts according to Appendix No 1.

3. Method

For this study, the research paper was done in a quantitative research method. On the basis of data collection and preliminary data processing, the research paper was executed with the following steps:

Step 1: The research paper involves collecting descriptive statistics to find out the proportion of respondents and determine the number of samples. The research paper has collected data from 349 people living in Hanoi city (through direct survey combined with online) to conduct observations. Observed variables are used a 5-point Likert scale (from

completely disagree to completely agree) to measure. After coding, cleaning, the data is included in the analysis.

Step 2: Use the reliability test method of Cronbach's Alpha to check the rigor and correlation between the observed variables, thereby removing the unsuitable variables and keeping the relevant variables in the research model. Variables with coefficients of Cronbach's Alpha > 0.6 and Corrected Item - Total Correlation > 0.3 will be kept.

Step 3: The research paper uses EFA (Exploratory Factor Analysis) to reduce a set of many interdependent measures into a smaller set of factor variables so that they are more meaningful but still contain most of the information content of the original set of variables.

Step 4: Finally, the research paper uses multivariable linear regression analysis, the aim is to estimate the value of the dependent variable Waste Classification (WC) on the basis of the values of the given independent variables and test the research hypotheses. From the results of the regression model analysis, the research paper discusses the research results and finds solutions to overcome the notable problems and improve the garbage classification of people in Hanoi city.

4. Results

4.1. Descriptive statistics

According to the results of descriptive statistics the team has analyzed, the survey sample has no significant difference in gender with the male-female ratio (the number of female residents participating in the survey is 52.4% while that of the male residents is 47.8%). In addition, the majority of respondents were between 18 and 25 years old (47%) and 26 to 40 years old (26.6%). Finally, the majority of residents participating in the survey do not have the habit of sorting garbage with a rate of up to 62%, so it is representative of the whole.

4.2. Cronbach's Alpha test

The results of Cronbach's Alpha test in Appendix 2 below show that, out of 25 variables analyzed, there are 20 observed variables of the factors that achieve Cronbach's Alpha coefficients ranging from 0.61 to 0.865 and Corrected Item - Total Correlation > 0.3 . Thus, there are 5 unsatisfactory observed variables that were removed in the research paper, including SN2, SN3, SN6, LS3, KN5. Appendix 2 shows that 20 variables representing 7 factors are completely consistent and satisfactory. Therefore, we keep the 20 observed variables that satisfy the conditions to proceed with the next steps of analysis.

4.3. Exploratory Factor Analysis

When the study conducted the EFA analysis, the results showed that the KMO value = 0.805 (Sig. = 0.00), so the data used for factor analysis is appropriate. With the analysis results from the software, we can extract 7 factors that have the best value of summarizing information in order including: Subjective norm (4 variables); legal system (3 variables); knowledge (4 variables); expectations (3 variables); attitude (2 variables); propaganda activities (2 variables), in which 2 observed variables PBC1, PBC2 of the observed scale

Perception is unsatisfactory because the difference of the 2 loaded factors is less than 0.2. The research paper also received the Eigenvalue = 1,148 > 1 and the total extracted variance (Cumulative %) = 70.744% > 50%, which proves that 70.744% of the variation of the data is explained by 7 measurement factors through 18 observed variables is completely consistent.

4.4. Results of regression analysis and test

After analyzing EFA, the research paper used a regression analysis, the regression results are shown in Appendix 3 below.

Appendix 3 shows that the given regression model is relatively consistent with the 95% confidence level. This shows that the more favorable the factors are, the more satisfied businesses are when using e-tax services. The coefficient R^2 is 0.489, showing that all 6 factors (SN - Subjective norm, LS - Legal system, KN - Knowledge, EXP - Expectations, AT - Attitude, PA - Propaganda activities) have a significant impact, in which attitude, legal system and knowledge are the three most influential factors. Besides, the adjusted R^2 index is 0.481, which explains 48.1% of the variation depending on the satisfaction level of enterprises when doing waste classification, which is predetermined by the independent variables in the model with 51.9% of the remaining variation explained by other variables.

From the results obtained after running the linear regression model, the research paper derives the following equation with a dependent variable WC (Waste Classification):

$$\mathbf{WC = 0.028 + 0.280*AT + 0.236*LS + 0.198*KN + 0.106*SN + 0.091*PA + 0.073*EXP}$$

The results show that all variables have a positive impact on customer satisfaction when using e-tax services and are statistically significant (Sig. is less than 0.05), with AT factor (Beta = 0.28).) having the strongest and most positive impact on user satisfaction. Next is the factor of LS (Beta = 0.236) and KN (Beta = 0.198) which also have a large impact on user satisfaction. SN and PA factors with Beta level equal to 0.106 and 0.091 respectively, have a positive effect and are in descending intensity. Finally, the factor EXP (Beta = 0.073) has the weakest positive impact on customer satisfaction when using e-tax services.

The study carried out other tests, the results showed that the model does not occur multicollinearity (VIF coefficients of all variables are < 2), does not occur autocorrelation and is completely consistent with the data. From the analysis above, it can be concluded that the theoretical model is suitable with the research data and accepts the research hypotheses H1, H2, H4, H5, H6, H7.

5. Discussion and conclusion

5.1. Discussion

Through a linear regression model and data source collected from more than 300 people in Hanoi city, the research paper has found out the influence of these factors on people's garbage sorting activities. The results show that there are 6 main factors that all affect in the same direction on the implementation of garbage classification of people in Hanoi city. The influence of the factors is arranged in descending order with the following meanings:

Attitude factor: Attitude factor has 2 observed variables, in which “People feel interested in sorting garbage” is the observed variable with a greater influence than “Garbage segregation is the responsibility of each individual”. Thus, if people feel more interested and responsible for garbage classification, the number of people sorting garbage in Hanoi city will increase. However, in fact, most people in Hanoi city do not have a positive attitude towards garbage classification. They believe that the implementation of garbage classification is the responsibility of the whole community, it does not have a certain impact and is not related to them personally. This explains the fact that there are still a large number of people in Hanoi who have no intention of doing garbage classification.

Legal system factor: In the observed variables of the Legal System (LS) factor, the observed variable: "Residents agree and comply with the state's laws on garbage classification" has the highest value. The largest value, followed by “The regulations on the process and system of treating the local waste are reasonable and effective” and finally “The State has been closely involved in promulgating legal regulations on garbage classification”. Thus, the more drastic the legal regulations on garbage classification are implemented by the state and competent officials, the higher the percentage of people in Hanoi city who perform waste classification.

Knowledge factor: Among the observed variables of the Knowledge factor, the variable "Residents know to distinguish the symbols and colors of the garbage sorting bins" has the greatest influence, followed by "Residents know to distinguish the basic types of waste" and finally the 2 observed variables "Residents know to distinguish the basic types of waste" and "Residents know where to collect each type of waste". This shows that the more people understand the basic knowledge in the field of garbage classification such as distinguishing the symbols on the trash can, recognizing the basic types of garbage, understanding the classification and treatment process after collection, the more inclined to perform garbage classification.

Subjective norm factor: Among the observed variables of the Subjective norm factor, the variable "Family members have a habit of sorting garbage" has the largest influence, followed by 2 important variables, respectively “People around residents always talk well about garbage sorting behavior” and “Residents’ friends support/encourage garbage sorting”, and finally “Family members support/ encourage garbage sorting”. This shows that the more people receive advice and encouragement from relatives, friends and people around them, the more they tend to do garbage classification.

Propaganda activities factor: In which, the variable "Propaganda activities about garbage sorting have helped people to raise awareness about this behavior" has the highest rating and has a greater influence than the variable: “Propaganda activities on garbage classification motivate people to do this behavior.” Thus, the more propaganda activities to raise public awareness and create motivation for garbage classification, the higher the number of people doing garbage classification in Hanoi city.

Expectation factor: The Expectation factor represents 3 observed variables, in which the variable "Residents expect that the habit of sorting garbage will bring good values to the environment" is rated the highest, next is the variable "Residents expect the habit of sorting garbage will bring good values to themselves", finally "Residents expect to receive recognition, respect and love from society when spreading spread the habit of garbage sorting". This shows that, if people expect garbage sorting to contribute to the environment or will receive appropriate rewards and recognition, they will tend to do more active garbage classification.

5.2. Conclusion

On the basis of theoretical research and evaluation models of human psychological behavior, the research paper has found and evaluated the main factors affecting the implementation of garbage classification of people in the city of Hanoi. The research results show that the attitude factor has the most positive and strongest impact on the people's implementation of garbage classification, followed by the legal system factor, the knowledge factor of the people about garbage classification, subjective norm and finally propaganda activities and expectations. This result is similar to previous studies, the results also confirm that the policies of the state and the authorities to improve attitudes, knowledge and widely disseminate information about the classification of garbage in particular and the environment in general to the people is very important.

In fact, the number of people sorting garbage in Hanoi city is not high. Therefore, some specific recommendations are as follows:

● For state management agencies

State management agencies need to supplement and strengthen regulations on severe penalties and sanctions to be subject to cases of intentional failure to classify garbage and obstructing behaviors for the State's management and inspection activities in the field of environment for households in Hanoi city. In addition, the management agencies also need to supplement the reward and commendation regimes for individuals with outstanding performance in supporting the state in setting up innovative and effective regulations and solutions with a positive impact on the situation of waste segregation. State management agencies can provide financial support, infrastructure and facilities to help implement and actualize new solutions. This will create a great motivation to promote notable individuals, from which, more and more great contributions will have a positive impact on the socialization of people's garbage classification.

● For some other related agencies

First, educational and training institutions, especially the primary, secondary and high school levels, need to strengthen the integration of garbage classification knowledge. At the same time, schools need to deploy and diversify practical activities inside and outside the school, giving students more opportunities to experience and apply the knowledge about garbage classification they have learned. For students, higher education institutions and colleges need to further strengthen the organization of seminars and projects on the environment, organize voluntary activities to sort waste at locations in Hanoi city.

Second, media agencies need to further promote propaganda activities for people in Hanoi city. The transmission of information needs to be done synchronously and optimized on many different media. Media agencies need to promote propaganda on current social networking platforms and use leaflets, banners and slogans to raise public awareness and call on people to separate their garbage.

• *Contribution of research paper*

The research paper is a scientific product with the aim of determining and finding out the factors affecting the garbage classification of people in Hanoi city. The research paper has applied many theoretical models, methods including qualitative and quantitative methods on the basis collected from people aged 18 to 70 years old in Hanoi city. This study will be a reference source for authors, scientists, etc. related to the environment, waste, authorities of Hanoi city and serve as a basis for similar studies.

Abstract

The global economy is developing at a rapid pace, but this progress is accompanied by severe environmental consequences, posing a major problem for countries and policymakers seeking appropriate solutions, especially in the context of the COVID-19 pandemic's long-term impact and economic instability caused by conflicts and political fluctuations. We believe that carbon taxes are a macro factor contributing to changes in the inflation rate. Therefore, this paper aims to estimate and analyze the impact of carbon taxes on inflation and their level of influence on the relationship between oil prices and inflation. We anticipate that carbon taxes can alleviate inflation pressure caused by an increase in oil prices. Our research provides valuable information for policymakers to adopt a dual approach of protecting the environment while stabilizing inflation. The results of our research models demonstrate that carbon taxes have a significant impact on inflation and can mitigate the adverse impact of oil prices on inflation. Overall, these findings have important implications for countries devising economic and environmental policies, serving as a foundation for reference and discussion to guide the development of environmental protection and economic policies.

Keywords: *carbon taxes, climate change, inflation, oil prices*

1. Introduction

Oil and other fuels are currently a choice of vital resources for the global economy since it is appropriate in nearly all economic areas. They are used for economic and social activities such as production, transportation, ect. And these activities cause carbon emissions, which are one of the elements that cause climate change. Any changes in oil prices can impact both microeconomic choices and macroeconomic policies (Korhan, Vahid, and Nigar, 2015). Moreover, oil prices also have a prime impact on the fall and rise of

inflation in any country throughout the world. Hooker (2002) separated his research period (1962 - 2000) into two terms to ascertain the connection between inflation and oil prices. He found that in the first period (1962-1980), the price of oil significantly influenced inflation, except during the second phase (1981-2000). Trehan validated Hooker's studies in 2005 by researching a similar issue and reaching the same conclusions. Additionally, Bermingham (2008) investigated Ireland's meager free economy and discovered the influence of rising oil prices on inflation. Jacquinet et al. (2009) investigated a similar problem for the Eurozone and discovered that oil price fluctuations have a significant impact in short-term inflation forecasting, even supposing the impact is much more complicated as an eventual outcome.

Previous researches have shown that the carbon taxes accomplish their purpose of lowering emissions such as studies by Martin, De Preux, and Wagner (2014), Andersson (2019); Murray and Rivers (2015), for Canada; Lin and Li (2011), and Best, Burke, and Jotzo (2020), for Europe. McKibbin, Morris, and Wilcoxon (2017), for example, considered a \$15 carbon tax established in America and discovered that it generated a 0.8 percent escalation in inflation during the initial year of the program. This is, as far as we know, the initial research to validate the influence of a carbon price on inflation. Moessner (2022) investigated the impact of carbon dioxide emissions on inflation and showed that higher carbon dioxide emissions can be associated with higher inflation at the country level. This suggests that climate change policies would not lead to higher inflation.

To the best of our knowledge, there is no study researching the causality of carbon taxes, oil prices and inflation rate. To generalize, this study examines how carbon taxes and oil prices are affecting inflation in 22 countries, both developing and developed ones, spanning all continents, including Europe, Asia, America and Africa, by annual frequency, based on the largest currently available data set of countries participating in the pricing and implementing the policy of imposing carbon taxes on each ton of CO₂ emitted into the environment. This research uses secondary data collected from Datastream and other reliable sources with unbalanced table displayed for the period from 1991 to 2021. In an effort to slow down the process of climate change, many countries levied a tax on the amount of carbon emissions, which are emitted by using energy sources such as oil. A climate policy scheme which can reduce carbon emission is carbon taxes. Some countries keep carbon taxes unchange in several years such as Chile. However, most of countries in our research sample change the carbon tax each year because it effectively reduces the amount of carbon emissions and support for the target of net zero emissions. Revenue from carbon taxes might be also reinvested in political choice for climate purposes, such as investing in inventing low-carbon technologies or other low-carbon energy replacing fuels. We wonder "If inflation is caused by a rise in oil prices, can we raise the price of taxes on carbon emissions both to cut emissions and to stabilize inflation?" For these reasons, we conducted this research: ***“Carbon Taxes and Oil Prices: Driving Inflation Up or Down?”*** to examine whether carbon taxes affect inflation as well as how carbon taxes impact on the adverse relationship between the price of oil and inflation. Our study proposes a new method for measuring how oil prices affect inflation under the context of imposing a carbon tax on the amount of carbon emitted into the environment.

2. Literature Review and Hypotheses development

2.1. Literature Review

2.1.1. Climate change policy and carbon emission reduction plan

Nearly all nations have enacted climate actions (Eskander and Fankhauser, 2020). Thus, a number of climate advisory groups have been built up during the past several decades (Averchenkova et al., 2021). The wording of international climate change discussions is vulnerable to lobbying, and even when agreements are reached, nations occasionally break their commitments or make insufficient pledges. One of the crucial factors of climate change is the decrease of carbon emissions (Hong et al., 2022). The findings indicated that the carbon emission reduction (CER) plan has stringent conditions for acceptance and that executors of the CER plan must be included in the planning process. The adoption of the growth of clean industries and low-carbon technology may help optimize and modernize industrial construction, increasing industry variety and synergy while lowering the dependency of urban expansion on natural resources under strict emission reduction targets.

2.1.2. Carbon pricing mechanisms and the impact of levying carbon taxes

A technique for reducing greenhouse gas emissions is carbon pricing. The governments do not use repressive instruments but provide a market mechanism for emission facilities. This leaves manufacturers with a choice between reducing emissions to avoid paying high prices or continuing to emit but paying a fee for their emissions. Two main carbon pricing mechanisms are Emission Trading System (ETS) and Carbon taxes (CT). However, in this research, we only focus on carbon taxes. There is an obvious difference between ETS and CT: the carbon taxes' emission reduction results are not predetermined, whereas the trading in ETS emissions credits is. Creating a worldwide carbon tax to supplant service and income taxes was pioneered by Finland in 1990. Norway imposed carbon taxes in 1991, covering 65 percent of all CO₂ emissions. Sweden started imposing carbon taxes in 1991. Between 1987 and 1994, the country's CO₂ emissions decreased by 600-800 million tons, or 13 percent in total. The United Kingdom (UK) imposed an extra 15 percent tax in 2001 as a result of climate change, which affected taxation standards in the public and commercial sectors that are based on energy prices. Funding for energy efficiency and conservation technologies came from the 0.3 percent of income tax revenue that was given back to the employers' national insurance accounts.

2.2. Hypotheses development

2.2.1. The relationship between carbon taxes and inflation

Several scholars have examined how carbon prices might affect the overall economy. According to Kaenzig (2021), ETS carbon price surprises in Europe, carbon pricing, and related carbon policies have a positive impact on emissions reductions, assisting in meeting emission reduction targets and softening the transition to climate change, but doing so must come at a cost, which is related to energy prices and consumption. McKibbin et al. (2021)

found that a carbon price only temporarily affects inflation using simulation models. The advantages of continuous innovation in renewables in response to carbon pricing, reduced power prices, and increased energy efficiency, however, might offset these larger inflationary pressures, which could also cause a decline in the share of energy contained in the CPI consumption basket, according to Andersson et al. (2020). According to Konradt and Weder di Mauro (2023), carbon taxes did not appreciably boost inflation, with dynamic impacts estimated to be near zero in most scenarios. Instead, they found support for relative price increases, which increased the cost of energy while leaving other goods and services unchanged. For the subsamples of Canada, they found slightly deflation responses in Canadian provinces, with an increase in energy prices having more offset by a fall in the prices of services and other non-tradables. To summarize, the available analysis of how carbon prices affect the economy is still ambiguous and contentious. Our study contributes to this topic by determining the influence of carbon prices on inflation and the variables that influence inflation, with the expectation that carbon taxes would have a positive effect on stabilizing inflation. Therefore, our first hypothesis is given:

H1. The carbon taxes help reduce the inflation rate.

2.2.2. The relationship between oil prices and inflation

Many studies have implied that there is a pass-through between oil prices and headline inflation, although the effect is weak, cyclical, and diminishing with time. According to Blanchard and Galí (2007) research, inflation and activity were significantly more affected by oil price shocks up to the mid-1980s than they were afterwards. They place the blame for this on the weakening of wage rigidities, the increasing credibility of monetary policy, and a drop in the proportion of oil in consumption and output. Similar findings are reached by De Gregorio et al. (2007), who claim the pass-through was five times as powerful before 1980 versus after (when a 10 percent increase in oil prices results in a 0.3 pp rise in inflation). Once again, this research will estimate the effect of rising oil prices on the rate of inflation, which is the basis for examining the connection among carbon taxes, oil prices, and the inflation rate.

H2. Oil prices directly make the inflation rate increase.

2.2.3. The relationship among carbon taxes, oil price and inflation

Baffes et al. (2015) have suggested that temporary drops in worldwide inflation have been observed after drops in oil prices. Falling oil prices also cause a decrease in overall energy costs since they drive the prices of competing energy products to drop and lower the cost of producing electricity using oil. Hamilton demonstrated in a number of works (see, for instance, Hamilton (1983, 1996)) that the majority of the United States depressions were anticipated by increasing the oil price, indicating that oil price hikes are one of the main causes of recessions. The advantages of continuous innovation in renewables in response to carbon pricing, reduced power prices, and increased energy efficiency,

however, might offset these larger inflationary pressures, which could also cause a decline in the share of energy contained in the CPI consumption basket, according to Andersson et al. (2020). Moessner (2022) investigated the impact of carbon dioxide emissions on inflation, his study suggests that implementing climate change policies does not lead to higher inflation. Moreover, higher carbon dioxide emissions can be associated with higher inflation at the country level. His study suggests that climate change policies would not lead to higher inflation. We support the scheme to control carbon emission such as carbon taxes, which help to reduce the amount of carbon dioxide emissions, therefore can help to control inflation. Konradt and Weder di Mauro (2023) showed that any inflationary effects of carbon taxes are limited to headline inflation and do not spread to core inflation. Although they discovered modestly deflationary reactions in Canadian provinces, the findings in Europe hint at moderate and imprecisely measured effects. In general, empirical data from European countries and Canadian provinces give scant support for the inflationary impacts of carbon pricing. Understandably, this research showed no change in inflation but there were other explanations that suggest the existence of an inflationary reaction, namely deflation when imposing a carbon tax. Firstly, British Columbia has adopted a tax scheme that causes families with high incomes to consume less products and services. Secondly, levying a carbon tax leads to increased energy costs, which forces manufacturers to lower the net present value of products using lots of energy, resulting in reduced pricing. Thirdly, consumers will tend to utilize fewer energy-intensive products and services, leading to greater supply than demand, which will be a surplus over demand and cheaper pricing. To the best knowledge of the authors, there is currently no clear evidence relating to the connection between oil price and inflation rate in the presence of the carbon tax factor. As a result, the authors conducted this research to go over the influence of carbon taxes on inflation as well as the link between inflation and oil prices, thereby providing useful reference data to policymakers in their efforts to stabilize inflation. Our last hypothesis is given:

H3. The carbon taxes mitigate the adverse effects of the rise in oil prices on inflation.

3. Method

Research data consists of 22 advancing and developing countries in the 1991-2021 period, including 327 observations shown in the form of an unbalanced table. With the carbon tax is chosen as the main explanation of the models, two following equations:

$$(1) \text{INF}_{i,t} = \beta_0 + \beta_1 \text{INF}_{i,t-1} + \beta_2 \text{CT}_{i,t-1} + \beta_3 \text{OIL}_{t-1} + \beta_4 \text{CONTROL}_{i,t-1} + \mu_i + \varepsilon_{i,t}$$

$$(2) \text{INF}_{i,t} = \beta_0 + \beta_1 \text{INF}_{i,t-1} + \beta_2 \text{CT}_{i,t-1} + \beta_3 \text{OIL}_{t-1} + \beta_4 \text{OIL}_{t-1} \times \text{CT}_{i,t-1} + \beta_5 \text{CONTROL}_{i,t-1} + \mu_i + \varepsilon_{i,t}$$

Where *i* and *t* respectively refer to country and time. The dependent variable $\text{INF}_{i,t}$ is the annualized percentage change in a consumer price index extracted from the Datastream for country *i* at time *t*. The key independent variables are proxied to observe macroeconomic factors' effects such as carbon taxes, global oil prices on inflation. A detailed list of variables, definitions, and sources can be found in Table 1.

Table 1. Variable definitions

Variables	Measurement	Sources
Dependent variable		
INF	Change in consumer price index (CPI) over the previous year	Datastream
Main explanatory variables		
OIL	Change in global oil price over the previous year	Macrotrends and Authors' calculation
CT	Change in the price of carbon tax over the previous year	World Bank and Authors' calculation
Interactive variable		
OIL×CT	Interactive between change in global oil price and change in carbon tax	Authors' calculation
Control variables		
OUTPUT	The distinction between actual and prospective output (the yield gap percentage)	Datastream
M2	M2 money supply growth over the previous year	Datastream
REER	Change in the real effective exchange rate index over the previous year	World Bank and Authors' calculation
TRADE	Trade surplus and trade deficit (dummy variable)	Datastream
PPI	Change in the producer price index from the previous year	Datastream

Source: Compiled by the authors

Firstly, to minimize the impact of outliers, the variables are winsorized at 2% level. Secondly, we used different regression methods including Pooled ordinary least squares regression (Pooled OLS), fixed effects model (FEM), random effects model (REM) to choose the best one. After this progress, we find that FEM is the most suitable model among the three of them. Thirdly, we use FEM with robust standard errors to compare and validate the robustness of our models. We also use the Breusch and Pagan Lagrangian to test heteroscedasticity. Finally, we consider that there are endogenous variables in our models that make the results unreliable and inaccurate. One of the causes of endogeneity is the concurrent effect between the dependent and independent variables, and it is possible that the model has encountered this cause. To solve endogenous variables and heteroscedasticity, we use system generalized methods of moments (S-GMM) developed by Arellano and Bover (1995) and Blundell and Bond (1998).

4. Results

As an outcome of the Pearson correlation coefficient matrix between the variables used in this study, most of the independent variables are correlated with dependent variables, in which the variables OIL, OUTPUT, M2, REER, and PPI are positively correlated with INF. The variables CT and TRADE are negatively correlated with INF.

We used Pooled OLS and FEM to regress the models and simultaneously test their robustness. However, we consider that there are some endogenous variables that make the results incorrect and unreliable. The results need to be validated by using another econometric method for certainty. Therefore, we conduct estimation of three models using the S-GMM method, which helps us handle endogenous problems, double-check the previous results using Pooled OLS and FEM, and give out the best outcomes for this research. To ensure that the S-GMM method is used correctly for estimating models, users should be aware of two tests. The first is the Hansen Test to check the appropriate level of the group of instruments used in models. The Hansen test's null hypothesis is that the instruments are valid. Table 2 shows that models (1) and (2) have p-value of the Hansen test greater than 5% and the number of instrument variables is 19, 15, respectively. This amount is less than 22 groups of countries. The outcomes of the Hansen test and instrument variables indicate that our models fulfill this condition. The second condition of using the S-GMM method with the null hypothesis is that there is no autocorrelation of order 2, which means the p-value (AR(2)) must be higher than 5% to accept this hypothesis. From the last line in table 2, p-values (AR(2)) for two models are 0.504 and 0.873, respectively, which are all higher than 5%. As a result, the research models have no autocorrelation of order 2. Because the models satisfy the Hansen test's two hypotheses, we can regress them using the S-GMM method.

The S-GMM method provides similar results as the Pooled OLS and FEM methods. The difference is that most of the variables become more statistically significant. Inflation has been influenced by the changes in historical carbon taxes and the price of oil. Specifically, the higher changes in carbon taxes will make the inflation level decrease. The evidence is that the regression coefficient of $CT_{i,t-1}$ is negative and significant at the 5% or 10% levels. In the S-GMM method, an increase of 1 percentage point in the carbon taxes will give rise to a 0.0076 percentage point decrease in the inflation rate in model (1), which is the same effect as model (2).

After regressing model (1) and examining the effect of CT and OIL on INF, we added the interactive variable $OIL_{t-1} \times CT_{i,t-1}$ in model (2) to study the relationship among the carbon taxes, oil price, and inflation. The variable $CT_{i,t-1}$ in model (2) are more impactful than the one in model (1), which means that an increase of 1 percentage point in the carbon taxes will lead to a 0.0329 percentage point decrease in inflation. In contrast with the carbon taxes, oil, which represents global oil prices, produces positive results. In model (1), an 1 percentage point increase in the price of oil causes an increase in inflation of 0.0167 percentage point, which is reasonable both in academic research and in practice. The increase in oil prices will raise logistics costs, causing goods and services to become more costly. $OIL_{t-1} \times CT_{i,t-1}$ in model (2) negatively affects INF_t at the 5% levels of statistical significance. With the regression coefficient of -0.0582 of $OIL_{t-1} \times CT_{i,t-1}$, we can explain that the short-term bullishness of the oil price will drive the inflation rate to rise. However, in the context of

levying the carbon taxes, the positive effect of a higher oil price on the inflation rate will be mitigated. Our results from S-GMM are similar to the one of Konradt and Weder di Mauro (2023) in the case of Canadian provinces. However, we fully support that levying carbon tax will reduce inflation with a 1-year lag. And, we also find that carbon taxes positively mitigate the adverse influence of oil price increase on inflation rate. Therefore, our hypotheses 1 and 2 are demonstrated and accepted. Besides the OIL_{t-1} , $CT_{i,t-1}$, interactive variable $OIL_{t-1} \times CT_{i,t-1}$, control variables such as $OUTPUT_{i,t-1}$, $M2_{i,t-1}$, $REER_{i,t-1}$, and $TRADE_{i,t-1}$ are statistically significant at the 1% level by using the S-GMM method. For further details, the intention in the previous year's money supply will contribute to a rise in the current year's inflation rate. The variable TRADE in model (1) is significant at the level of 1%, meaning that net export countries have a lower inflation rate than net import countries. These results are reasonable because importing goods and services from foreign countries will indirectly bring inflation factors into domestic markets, such as higher prices, changes in the exchange rate, increase in demand, etc.

5. Discussion and conclusion

Our study outcomes match up with our given expectations. The results indicate that the global oil price and carbon taxes significantly impact inflation in both developing and advanced countries. The model of lag variables shows that levying carbon taxes mitigates the acceleration of inflation caused by the higher oil price. Moessner (2022) also studied that higher carbon emissions are associated with higher inflation and nations with better climate policy rankings tend to be associated with lower inflation across countries. Based on these results, we can explain that carbon taxes help reduce carbon emissions, and therefore help mitigate the adverse effect of higher inflation. Using the interaction variable $OIL_{t-1} \times CT_{i,t-1}$ in model (2), we can see that the impact of oil prices on inflation decreases. This is an optimistic and meaningful result. There are some reasonable explanations for the deflation effects of implementing carbon taxes. Firstly, levying carbon taxes can depress household income and force them to cut back consumption, which leads to a downward trend in price. Secondly, levying carbon taxes then intensifies investing and producing less energy-intensive goods and services and gradually does not use much energy for producing, which may cause less use of nonrenewable energy sources. Based on this outcome, the enforcement of a carbon tax to accelerate the movement to zero carbon is not constrained by considering the inflationary impact. This is significant since carbon pricing regimes have been demonstrated to reduce carbon emissions. The research's findings are in line with the author's expectations relating to the government's policy as well as the stagnant economy at that time.

Regarding the case of Vietnam, the government has made considerable efforts in establishing and implementing domestic laws and strategies to speed green growth. However, the biggest worry is leading to expensive goods because of higher tax expense and then inflation increase. Our research can help policymakers answer this question. The authors agree that carbon taxes can accelerate the prices in the first period of levying but it can help the price decrease after that to avoid paying high taxes or buy carbon credits from

others. Therefore, the demand for using oil and other unrenowable fuels will decrease as people are aware of the adverse effect on their spending. Therefore, raising oil prices will not accelerate the inflation rate like before.

In conclusion, according to our findings, levying carbon taxes not only does not have a pessimistic impact on the aim to reach net zero emission in 2050 but also helps reduce the inflation rate and mitigate the effect of increasing oil price. The authors suggest that Vietnam accelerate the progress of establishing a carbon pricing mechanism such as carbon taxes in the near future. From the perspective of the political economy, the central bank should have supportive policies for the imposition of a country's carbon taxes. However, revenue from carbon taxes should not be reserved for any specific purpose, but it can contribute to reducing social costs, maintaining stable supply and demand, and serving as a useful subsidy when the domestic economy fluctuates.

Faculty of Transport Economics, University of Transport Technology, Hanoi, Vietnam

Abstract

This study investigates the impact of factors on the implementation of environmental management accounting (EMA) in manufacturing enterprises in Hanoi, Vietnam. This study employed a survey conducted in Hanoi manufacturing enterprises. Validity and reliability tests were carried out on the collected questionnaires. Data analysis was performed using SPSS 22. The results show that Level of Technology; Stakeholder Pressures; Perception of Manager; Accountant Qualifications positively impact on the implementation of EMA in manufacturing enterprises in Hanoi. Results of the study lay the groundwork for the application of EMA in Hanoi manufacturing firms in particular, and Vietnam in general.

Keywords: *environmental management accounting, environmental accounting, manufacturing enterprises, Hanoi.*

1. Introduction

Economic growth associated with ensuring environmental quality towards sustainable development is now becoming a trend and common goal of most countries in the world. Realizing the above goal, the Governments of countries including Vietnam have set increasingly strict requirements on environmental protection, forcing businesses to change their perception of environmental issues when conducting environmental activities. investment or production activities. This policy requires enterprises, not only producing products to meet the market demand but also to create environmentally friendly products, and fulfill environmental protection responsibilities such as limiting waste, cleaning up waste, or having to compensate for damage when causing environmental problems... In that context, environmental accounting was created to support enterprises to fulfill their obligations to the environment in the process of production and business.

Although environmental protection in economic development has been a concerned by the State as well as by environmental management agencies, up to now, environmental accounting in Vietnam has not been paid attention to, and current legal documents and accounting standards have not yet mentioned the organization of environmental accounting in enterprises. The current accounting system does not have regulations guiding enterprises in accounting and recording costs incurred related to the environment as well as revenue and

income. There are no effective tools in environmental management, in the operation of enterprises, legal documents, and environmental standards have not been synchronized...

Factors affecting the implementation of environmental management accounting in enterprises is a topic that attracts great attention from administrators and researchers. The examination of the variables influencing how environmental management accounting is implemented in businesses is carried out in many different countries such as Portugal, Australian, Malaysian, Thailand,... Ribeiro & Aibar-Guzman (2010) studied determinants of environmental accounting practices in local entities from Portugal; Christ & Burritt (2013) examined the state of the literature by evaluating whether the type of organizational structure could be used to increase knowledge of EMA use by Australian organizations; Setthasakko (2015) has discovered factors affecting the implementation of environmental management accounting in pulp and paper enterprises in Thailand; Mokhtar et al., (2016) measurement and identified factors affecting implement EMA of Malaysian public listed companies,....

Many studies have been conducted to explore the factors influencing the implementation of EMA, but the findings are still varied and inconsistent as a result of the research being conducted in various nations, fields, professions, and eras. Manufacturing enterprises are one of the industries that greatly impact the environment. With their sensitive characteristics to the environment, production and business activities will also have more impact on the environment. Therefore, to ensure their prestige, reputation, position, and production and business activities, manufacturing enterprises in Hanoi produce the products that impact the environment and are more likely to implement EMA. Moreover, there are few empirical studies on factors affecting the implementation of environmental accounting in manufacturing enterprises in Hanoi, where the implementation of environmental accounting is still voluntary demand for most enterprises.

Therefore, this study's aim is to identify the factors and quantify the level of influence of each factor on the implementation of environmental accounting in manufacturing enterprises in Hanoi, Vietnam. The results of the study will be useful to corporate executives and policymakers in environmental management accounting.

2. Literature review and research hypotheses

The factors affecting the adoption of EMA have been the subject of numerous studies, but the findings are still varied and inconsistent as a result of the research being conducted in various nations, fields, professions, and times.

Kokubu and Nashioka (2005) used a questionnaire survey to characterize corporate environmental accounting procedures in companies listed in the first section of the Tokyo Stock Market. The results showed that a well-established environment department actively engaged in decision-making across the firm; top and middle management awareness of environmental accounting concepts; and usage of specialist EMA tools affect to the environmental accounting procedures.

Ribeiro and AibarGuzman (2010) investigated the impact of three variables (organizational size, accounting regulation, and the level of development of environmental

management practices) on the extent to which a sample of Portuguese local organizations established a set of environmental accounting practices. They have discovered evidence indicating a positive and statistically significant relation between the level of development of environmental accounting practices and two of the factors (organizational size and level of development of environmental management practices).

According to Ferreira et al. (2010), EMA use is positively associated with process innovation but not with product innovation. However, there was no significant statistical relationship between the application of EMA and strategy. According to the study's findings, companies that engage in delicate industries are more likely to use environmental accounting.

Christ & Burritt (2013) have shown that environmental strategy, industry and enterprise size have an important relationship to the implementation of EMA in Australia. However, the organizational structure does not affect the adoption of environmental management accounting.

Setthasakko (2015) has discovered three primary factors influencing the adoption of environmental management accounting: top management roles, knowledge sharing and building corporate in pulp and paper companies in Thailand.

Mokhtar et al., (2016) measurement and identified factors affecting implement EMA of Malaysian public listed companies. The results show that complying with environmental regulations is more important than incorporating EMA information into performance measurement, control and reporting.

Susanto (2019) concludes that senior managers' environmental awareness, business characteristics, and qualifications of accountants have a significant influence on environment accounting.

The study on this issue in Vietnam has been verified by Ha (2022) when analyzing the factors affecting the implement EMA of manufacturing enterprise in Vietnam. The research shows that the implement EMA have a significant correlation with the pressure from stakeholders; Business sector; Qualification of accounting staff; Managers' perception of environmental accounting; and Enterprise size. Duong et al., (2022) surveyed 321 chief accountants and managers working for 200 manufacturing enterprises in Da Nang, Vietnam. Research results showed that technology level, enterprise characteristics; performance pressure; accounting staff qualifications, and managers' awareness affecting EMA implementation.

Based on the empirical research on EMA, the authors set up 5 research hypotheses to clarify the significance of the factors influencing the application of EMA in Hanoi's industrial businesses is as follows:

Business characteristics: Research by Ferreira et al., (2010), Mokhtar et al., (2016) indicate that companies with sensitive business sectors such as the chemical, mining and metallurgical industries are more likely to apply environmental accounting than all other companies considered in the study. Manufacturing companies with environmentally sensitive business areas are in high demand in the implementation of environmental

accounting because they often incur unanticipated risks, impact on the environment, causing enterprises to face many compensations incurred, increasing costs, affecting the interests of enterprises. This result is also proved by the research of Deegan & Gordon (2001), Christ & Burritt (2013). Christ & Burritt (2013) have demonstrated that the industry has a positive relationship to the implementation of environmental accounting. With the above analysis, the business sector of the enterprise influences the implementation of environmental accounting in manufacturing enterprises. Therefore, the first hypothesis is established, as follows:

H1: The business characteristics positively impact on the implementation of EMA in manufacturing enterprises in Hanoi.

Level of technology: In order to draw conclusions about the capacity of information technology to significantly influence environmental accounting in Indonesia, Susanto (2019) analyzed different obstacles that could prevent the effective functioning of environmental accounting information systems. The importance of supporting information technology is also emphasised by this study. To completely comprehend the true nature of technological competence in environmental accounting, a complex infrastructure and a highly-skilled personnel are required. According to Jasim & Raewf (2020), the usage of information technology causes considerable changes in accounting practice. Users can complete tasks more effectively thanks to information technology. Accountants may no longer simply copy and assess financial data to serve as a foundation for decisions in the future. Therefore, the hypothesis proposed by the authors is as follows:

H2: Technology positively impact on the implementation of EMA in manufacturing enterprises in Hanoi

Accountant Qualifications: Accountants' qualifications are reflected in the skills, knowledge and the skills they acquire through education and training. Stakeholders can get financial and non-financial environmental information through environmental accounting. Accounting personnel must possess the necessary knowledge and abilities to record, present, and disclose environmental information in order to carry out this duty. To get around the limitations of traditional accounting, accountants must precisely assess and distribute costs, which is not an easy operation. According to Setthasakko (2010), the incorporation of environmental issues into accounting systems practices in Thai businesses can be constrained by a lack of environmental knowledge and expertise. Education level is one element influencing the company's decision to apply to EMA, according to research by Alkisher (2018). Based on the above analysis, the author considers that:

H3: The qualification of accounting positively impacts on the implementation of EMA in manufacturing enterprises in Hanoi

Stakeholder Pressures: The pressure of stakeholders mentioned in the studies of Kisher (2013), Jamil et al., (2015) when studying the impact of pressures from the community, from the press media or from government agencies on environmental protection standards will create pressure for enterprises to perform environmental accounting. Environmental reporting is increasing both in quantity and quality because

environmental accounting is increasingly spreading by imitating the behavior of one business to another to achieve the enormous benefits of sustainable development. Research by Zeng et al., (2012) showed that industries with many enterprises involved in environmental information disclosure activities will be able to disclose environmental information more. Based on the above analysis, the author considers that:

H4: Stakeholder Pressures positively impact on the implementation of EMA in manufacturing enterprises in Hanoi

Perception of manager: Senn and Giordano-Spring (2020) demonstrated that environmentally responsible businesses will have a higher environmental impact, resulting in increased environmental expenses and improved environmental cost awareness. Several previous research studies have indicated that senior management's attention and support are essential for any environmental management strategy to be successful (Setthasakko, 2010; Jamil et al., 2015). The ability of the management team and the backing of the administrators determine whether EMA implementation in businesses is successful or unsuccessful. One of the crucial elements in EMA practice is management perception, as managers have a say in policy decisions and environmental strategy in business operations (Kokubu & Nashioka, 2005). Business managers' lack of environmental awareness and active support for EMA preparation, on the other hand, can limit EMA implementation (Jamil et al., 2015). Based on the above analysis, the author considers that:

H5: Perception of management positively impact on the implementation of EMA in manufacturing enterprises in Hanoi

3. Method

Based on the review of previous scholars, we use the following model to clarify the significance of the factors influencing the application of EMA in Hanoi's industrial businesses, as follows (see Figure 1):

Figure 1. Research Model

With multiple regression model as follows:

$$IEMA = \beta_0 + \beta_1*BC + \beta_2*TECH + \beta_3*AQ + \beta_4* SP + \beta_5*PM + \epsilon$$

In which:

β_1, β_2, \dots is the regression coefficient, β_0 is the blocking coefficient, ϵ is the residual

Dependent variable

IEMA: Implementation of environmental accounting in manufacturing enterprises in Hanoi

Independent variables, including:

BC: Business Characteristics

TECH: Level of Technology

AQ: Accountant Qualifications

SP: Stakeholder Pressures

PM: Perception of Manager

The authors collected information from the questionnaire about the factors affecting EMA implementation. The research questionnaire is based on the study by Senn & Giordano-Spring (2020); Mokhtar et al. (2016); Susanto et al. (2019); Alkisher (2013); Fuzi (2019); Duong et al. (2022) and adjusted to suit the study object. Respondents answer questions related to EMA, Business Characteristics, Level of Technology, Accountant Qualifications, Stakeholder Pressures, Perception of Manager. Also, age, gender, job, firm size, email, education, and experience are included. These independent factors are assessed in this study using a 5-point Likert scale, with 1 being "Strongly disagree," and 5 being "Strongly agree." Each independent variable has a variety of questions listed in this section.

Business managers, chief accountants of Hanoi manufacturing companies with significant accounting knowledge, and managers with EMA knowledge operate as the research subjects and provide advice and assistance for the planning of each concept-related study. The setting was chosen as Hanoi because of major environmental problems. The respondents were management and accountant in 208 manufacturing companies. The total questionnaires distributed numbered 280, but the number of returned questionnaires was 226 from 208 companies. The data found that only 226 sets of data could be analyzed because many answered did not answer the questionnaire completely. To test the hypotheses, exploratory factor analysis (EFA), difference analysis (ANOVA), and exploratory factor analysis (EFA) were used to analyze, assess, and synthesize data from 267 samples using SPSS software

4. Results

4.1. Testing the reliability of the scale

As shown in Table 1, all factors and variables are acceptable since Cronbach's Alpha values for each variable are larger than 0.6 and the differences between the eliminated items are minimal.

The average correlation between all the components that comprise the scale is shown by Cronbach's Alpha. The corrected item-total correlation and Cronbach's Alpha coefficient are both above 0.4 in the results. The scale of subjective factors is therefore acceptable.

Table 1. Testing the reliability of the scale

Variables	Corrected Item-Total Correlation	Cronbach's Alpha if Item Deleted
Cronbach's Alpha of IEMA: .897		
IEMA1	.869	.835

4.2. EFA Factor Analysis

Exploratory factor analysis (EFA) helps examine the convergent value and discriminant value. EFA must satisfy the following requirements: factor loading > 0.5 ; KMO $\leq 0.5 \leq 1$; Bartlett test the statistical significance (Sig. < 0.05); percentage of variance in Extraction Sums of Squared Loadings $> 50\%$.

The KMO index is $0.757 > 0.5$ as a result of the factor analysis, which indicates that the data were absolutely suitable for this study. Results of Bartlett's test with Sig = 0.000 0.05. The observed variables do not generally related to one another, so the hypothesis H0 is rejected. Variables are therefore correlated with one another and meet the criteria for factor analysis. The outcomes also revealed that the 18 observed factors were divided into five groups. It may be concluded that these five factors contributed for 75,583% of the data variability because the value of the total variance retrieved = 75,583 $> 50\%$, which is acceptable. Finally, factor loadings are greater than 0.5, and there is no case in which the upload of both factors at the same time has a close load factor.

So, when analyzing EFA, factors maintain confluence and differentiation. Furthermore, there is no factor disruption, therefore it is impossible to switch up one question with another. Consequently, following factor analysis, neither of these independent components is increased nor decreased.

Table 2. KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.757
Bartlett's Test of Sphericity	Approx. Chi-Square	2832.335
	df	153
	Sig.	.000

Source: Data processing results of authors

There was a factor investigation done upon that 18 survey items. As a result, all items had factor loading values greater than 0.5. Moreover, there is no factor disturbance, therefore it is impossible to mix up one question with another. Consequently, following factor analysis, neither of these independent components is increased nor decreased. A total of 18 observed variables were organized into 5 groups of factors by the use of rotation.

4.3. Regression Analysis

The findings demonstrate that, at a significance level of 0.05, the regression model produces results that are comparatively consistent. The adoption of EMA is described by the fluctuation of the independent variables: Level of Technology; Stakeholder Pressures; Perception of Manager; Business Characteristics; Accountant Qualifications. with a R coefficient of 0.567, indicating a 56.7% variance of the dependent variable, IEMA. Other factors not taken into account by the model account for the remaining 43,3% variation in EMA adoption (such as ownership status, enterprise size, corporate culture, etc.).

There is no autocorrelation in the sample, as indicated by the Durbin-Watson statistic's value of 1.729. The findings demonstrated that ANOVA refers to the statistical significance of the used regression model. For the sig = 0.000 < 0.005, the result offers evidence that the model used is suitable for forecasting the outcome (see Table 5). The linear regression equation of the proposed research model after the regression analysis with coefficients described in Table 6 is shown as follows:

$$\text{IEMA} = 0.457*\text{TECH} + 0.120*\text{SP} + 0.182*\text{PM} + 257*\text{AQ} + \varepsilon_i$$

Table 4. Respondent Profile

Model Summary ^b					
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	.567 ^a	.321	.306	.83316855	1.729

a. Predictors: TECH, SP, PM, BC, AQ
b. Dependent Variable: IEMA

4. Discussion and Conclusion

The research results show that there is no correlation between business characteristics and the implementation of environmental accounting in manufacturing enterprises in Hanoi (Sig. = 0.757 > 0.05) (H1 is rejected). This result is contrary to the research hypotheses and studies of Chang and Deegan (2010), Jamil et al. (2015), Mokhtar et al. (2016). The reason could be due to a lack of regulatory incentives or enforcement mechanisms for implementing environmental accounting in Hanoi. If there are no regulations or policies that require or incentivize businesses to implement environmental accounting, they may not see it as a necessary or profitable investment.

The factor of technology level has the positive significance and impact on EMA implementation. This result is completely consistent in practice. Regression analysis

showed that the technology level had a positive and significant impact on implementation of environmental accounting in manufacturing enterprises. The beta value showed a coefficient of 0.457, with the Sig. of 0.000. Therefore, it can be argued that the technology level positively impacts the implementation of environmental accounting in manufacturing enterprises (H2 is acceptable)

Third, Implementation of environmental accounting in Hanoi industrial businesses is positively correlated with accountant qualification (accepting H3). The findings of the study show that when accountants' qualifications raise by one unit, EMA implementation in Hanoi manufacturing businesses rises by 0.253 units. This outcome is in line with the research done by Duong et al. (2020) and Setthasakko (2010). This study explains why companies with highly skilled and experienced accountants will aid in the smoother implementation of EMA.

Fourth, there is a relationship between relevant stakeholders and the application of environmental accounting in Hanoi's manufacturing facilities (H4 is acceptable). While the government issues several environmental and environmental accounting requirements, stakeholder pressure is an important aspect that will help promote the use of EMA in Hanoi's manufacturing firms. Also, the more investor and customer pressure there is on environmental issues, the more EMAs will be implemented in these businesses.

Fifth, the implementation of environmental accounting in manufacturing firms is positively correlated with manager perception (accepting H5). The beta coefficient of the manager perception variable is 0.182, and the accreditation sig is $0.001 < 0.05$. This result is similar to Jamil et al. (2015) and Kokubu & Nashioka (2005). In actuality, managers and business operators are the individuals who choose or take the lead in leading departments in the firm to use EMA. They are also the ones who are at the forefront of understanding the role of EMA.

In summary, through a set of data collected from Hanoi manufactured enterprises, the authors analyzed the impact of factors on the implementation of environmental accounting in manufacturing enterprises in Hanoi. Empirical results show that Level of Technology; Stakeholder Pressures; Perception of Manager; and Accountant Qualifications have a positive impact on the implementation of environmental accounting in manufacturing enterprises.

This study has enabled EMA implementation in Hanoi industrial businesses in an attempt to increase economic benefits, safeguard the environment, and promote sustainable development. Therefore, the Government of Vietnam should implement propaganda to raise awareness of environmental information disclosure for enterprises and issue strong enough administrative sanctions to encourage the disclosure of environmental information, in addition to issuing regulations on environmental accounting and complying with environmental regulations. Also, accountants must be completely qualified, professionalized, and have professional ethics on the environment and sustainable development if environmental accounting is to advance in the future. In order to develop high quality human resources to satisfy the requirements of society for sustainable development, closer access to international practices, environmental accounting should be part of the education systems for accounting - auditing majors at economic schools for undergraduate and master's degrees.

The scope of the study is still narrow, so it is possible to expand the scope to a wider area. In addition, the following studies can continue to analyze the confirmatory factor CFA to retest the model. At the same time, the implementation of EMA can be studied extensively with more factors affecting other scales.

Abstract

The objective of this study is to analyze and assess the impacts of green supply chain management (GSCM) on the business performance of Vietnamese textile enterprises. The study was carried out through a linear structural model (SEM) with 235 enterprises in the textile industry in Vietnam through direct investigation method and online survey. The results have shown that environmental protection in cooperation with customers and suppliers has a direct and positive impact on all three aspects of business performance. Furthermore, reverse logistics activities have a positive impact on the environmental performance of Vietnamese textile enterprises. In addition, the study also shows that there are differences in the impact on environmental performance of enterprises by different sizes and operating periods.

Keywords: *Textile enterprises, business performance, green supply chain management.*

1. Introduction

In a world focusing on environmental protection and building a green economy, the green supply chain is also a new direction for the development of businesses, helping enhance their competitive capability (Humphreys et al., 2003; Shu and Zhang, 2004; Lee et

al., 2009). Green supply chain (GSC) is gradually becoming the mainstream tendency aiming towards a sustainable development and core values in business performance of enterprises, in order to create common benefit for businesses and society as a whole. This development direction not only helps businesses maintain their position as well as increase their competitive advantage in the market, but also contributes to shaping a friendly and sustainable brand.

Business performance is the foundation of the business's reproduction and expansion. In the context of intensive economic integration, improving operational efficiency is an urgent issue that every business is concerned about. In the past, there have been many studies discussing the impact of green supply chain management (GSCM) on the performance of enterprises, but these researches are mainly conducted in countries with developed economies such as the United States or Europe. For developing countries like Vietnam, there are quite a few research works on this topic. Moreover, these studies are limited to a few industries, not comprehensive but only cover several certain aspects. Therefore, the responsibility to participate in or implement GSCM as well as the influence of GSCM on business performance has not been related and extended to all industries.

The textile and garment industry is one of the major export sectors of Vietnam, contributing dramatically to the economic growth of the country. In 2021, this industry contributed 40.4 billion USD to Vietnam's export turnover and witnessed a 8.9 percent growth, touched 44 billion USD in 2022 (Vietnam Textile and Apparel Association, VITAS, 2022). By 2022, Vietnam's textile and garment products have been exported to 66 countries and territories with 47-50 different items (Vietnam Textile and Apparel Association, VITAS, 2022). Despite making significant contributions to the economy, this industry has a high risk of causing environmental pollution in Vietnam. Cotton production for raw materials as well as the stages of washing, bleaching, dyeing and final cleaning require a huge demand for water resources. Additionally, emissions and solid waste are also major problems of textiles. Therefore, "greening" the textile industry is essential to ensure a sustainable development of future generations.

From these practices, it can be affirmed that GSCM is crucial and a prerequisite for Vietnamese textile enterprises to develop sustainably and participate in the global value chain. However, there is no research on the level of GSCM implementation in textile enterprises, what benefits that GSCM brings to these enterprises, or how GSCM affects their performance. Therefore, the research and evaluation of the impact of green supply chain management on the performance of Vietnamese textile enterprises in the current context is both theoretically and practically meaningful.

2. Theoretical basis

2.1. Theoretical basis

2.1.1. Green supply chain management

The research literature has generated much debate over the past few decades about the definition and scope of green supply chain management. Among them, the two most commonly used terms are green supply chain management and sustainable supply chain management (Ashby et al., 2012).

According to Zhu and Sarkis (2004), green supply chain management is understood as a combination of elements in corporate environmental management and supply chain management. Srivastava (2007) emphasizes that green supply chain management is “integrating environmental contemplation into supply chain management, including product design, material sourcing, manufacturing processes, delivery of final products to the customers as well as the management of the products after using”. This definition has been accepted and inherited by many later authors in the following research periods (Sundarakani et al., 2010; Wee et al., 2011; Wu and Pagell, 2011;...). Ahi (2013) defined green supply chain management as the creation of coordinated supply chains through the integration of environmental, economic and social factors into inter-organizational business chains, designed for efficiently managing materials, information, and capital flows for the procurement, production, and distribution of products or services to meet partners’ requirements and improve profitability, competitiveness and resilience of the organization in the short and long term. The reason why enterprises need to implement green supply chain management is because they are under pressure to minimize their impact on the environment and the ecosystem. Therefore, it can be simplified that green supply chain management is the integration of environmental management functions into inter-organizational activities, with three subjects including suppliers, businesses and customers.

Sarkis et al. (2011) emphasize that there are many organizational theories applied to the topic of green supply chain management, namely institutional theory, resource-based theory, stakeholder theory, transaction cost theory. However, in this topic, resource-based theory is the most suitable to explain the relationship between GSCM and business performance while other theories play the role of investigating the motivation for enterprises to participate in GSCM practice.

2.1.2. Business performance

Due to different perspectives, previous researchers have been unable to agree on a common concept of business performance:

According to Hui et al. (2008), the performance of an enterprise is considered as a composite efficiency, which is measured through: financial efficiency and operational efficiency. In which, financial efficiency is reflected through factors related to profit (ROA, ROE, ROS). Operational efficiency is reflected through indicators of labor productivity, level of commitment of employees to the enterprise and investment efficiency. Operational efficiency can be determined through the following indicators: Profit growth rate, revenue growth, return on equity.

From the perspective of profit maximization, according to author Tang Thi Thanh Thuy (2020): “Business performance of an enterprise is an economic category that reflects the utilization level of production resources, organizational management level of the enterprise to achieve the highest socio-economic goals at the lowest cost.” Authors Nguyen Thanh Do and Nguyen Ngoc Huyen (2001) said that: “Business performance reflects the utilization level of production resources (labor, raw materials, cash flow, machinery) in the output production process of the enterprise”.

Our research team identifies enterprises as a cell of the economy - society, so within the scope of this research, the team conducts an assessment of business performance based on composite efficiency. Accordingly, business performance is a category that reflects the level of the enterprise's use of aggregate resources to achieve the highest results at the lowest costs. The results are considered based on the following factors: production - business, capital attraction, investment, environmental and social protection.

2.2. Research model and hypothesis

On the basis of implementing resource-based theory and referring to previous studies, the authors propose a model with 6 independent variables corresponding to 6 factors affecting the performance of textile enterprises, including: Internal green practices of business (THXBT), environmental protection in cooperation with suppliers (HTNCC), environmental protection in cooperation with customers (HTKH), environmental supervision with suppliers (GSNCC), environmental supervision from customers (GSKH) and reverse logistics (RL). In order to maximize the reliability of the research results, the research authors add 3 control variables into the model, including: size of business, operating period of business and type of business. Meanwhile, the dependent variable - business performance - is measured by 3 components: Financial performance (HQTC), environmental performance (HQMT) and export performance (HQXK).

Research hypotheses:

Most previous studies have indicated that there is a positive relationship between internal and external green practices of enterprises and financial performance (Gil et al., 2001; Rao and Holt, 2005; Wong et al., 2012). Therefore, the authors propose the following hypothesis:

H1a: Internal green practices of enterprises have a positive impact on financial performance.

Several studies (e.g. Zhu & Sarkis, 2004; Yang et al., 2013; Laari et al., 2016; Zaid et al., 2018; Ahmed et al., 2020) have shown the implementation of internal green practices has a positive effect on environmental performance. Therefore, the authors propose the following hypothesis:

H1b: Internal green practices of enterprises have a positive impact on environmental performance.

Singh et al (2016) assert that the implementation of green practices will facilitate the export of products to various developed and developing countries with strict regulations on importing environmental products. Therefore, the authors propose the following hypothesis:

H1c: Internal green practices of enterprises have a positive impact on export performance.

Laari (2016) concludes that both environmental cooperation with customers and environmental cooperation with suppliers can directly lead to financial improvements. Therefore, the authors propose the following hypothesis:

H2a: Environmental protection in cooperation with suppliers has a positive impact on financial performance.

The literature review indicates that a large number of researchers agree that in a manufacturing environment, strong relationships with suppliers help improve environmental performance, including Geffen and Rothenberg (2000), Lee and Klassen (2008), Vachon and Klassen (2008), Gimenez et al (2012), Tachizawa et al (2015), Wang et al (2017) and Thongrawd et al (2019). Therefore, the authors propose the following hypothesis:

H2b: Environmental protection cooperation with suppliers has a positive impact on environmental performance.

Research conducted by Karrim and Bhuiyan (2020) suggests that cooperation with suppliers can reduce production costs, which also improves export efficiency. Therefore, the authors propose the following hypothesis:

H2c: Environmental protection in cooperation with suppliers has a positive impact on export performance.

Enterprises can better address environmental requirements and suggestions downstream by partnering with customers. This activity directly improves customer satisfaction and increases the reputation of the business in the market, which leads to financial performance (Wolf, 2011; Tang et al., 2012). Therefore, the authors propose the following hypothesis:

H3a: Environmental protection in cooperation with customers has a positive impact on financial performance.

There are many studies that support the existence of a positive correlation between customer cooperation and the environmental aspect of sustainable business performance, such as Diabat et al (2013), Zhu et al (2013) and Ahmed et al (2020). Therefore, the authors propose the following hypothesis:

H3b: Environmental protection cooperation with customers has a positive impact on environmental performance.

Teng et al (2014) indicate that customers in export markets tend to give preference to products that are manufactured and transported by procedures with less negative impact on the environment, as well as preferentially seeking products and services with environmental certification and other environmental protection standards (Choi and Lee, 2019). The fact that businesses improve their position in front of customers helps them create higher value. Therefore, the authors propose the following hypothesis:

H3c: Environmental protection in cooperation with customers has a positive impact on export performance.

Gimenez Cristina and Sierra Vicenta (2013) show that environmentally assessing suppliers can positively affect financial performance. Therefore, the authors propose the following hypothesis:

H4a: Environmental supervision with suppliers has a positive effect on financial performance.

The findings of Murray (2000), Theyel (2001), Klassen and Vachon (2003), Laari et al (2016), Khan et al (2018), Thongrawd et al (2019) and Ahmed et al (2020) all show that monitoring suppliers improves environmental performance. Therefore, the authors propose the following hypothesis:

H4b: Environmental supervision with suppliers has a positive impact on environmental performance.

Research by Wu et al. (2017) found that environmentally supervising suppliers can improve the quality of products and reduce environmental risks in businesses' supply chains. This can help enterprises increase export efficiency by improving the reputation and reliability of their products. In this study, the research team expects that there is a relationship between environmental supervision with suppliers and export performance.

H4c: Monitoring supplier environment has a positive impact on export performance.

Green et al. (2012) and Khan et al. (2018) both demonstrate that customer monitoring has a significant positive impact on environmental performance. Therefore, the authors propose the following hypothesis:

H5b: Environmental monitoring from customers has a positive impact on environmental performance.

A great deal of research has pointed out that effective reversed logistics management allows enterprises to reduce costs as well as improving customer satisfaction (Dowlatshahi, 2000; Franke et al., 2006; Rubio, Chamorro and Miranda, 2008; Chen, 2010; Weeks et al., 2010). Reverse logistics impact on the bottom line is clear to industries with return rates varying from between 5% and 20% (Daugherty, Autry, and Ellinger 2001) up to approximately 50% (Prahinski and Kocabasoglu 2006). From there, the authors propose the following hypothesis:

H6a: Reverse logistics has a positive effect on financial performance.

Since reverse logistics not only plays an important role in the closed supply chain in general (Govindan et al., 2015) but is also considered as an aspect closely related to the sustainable supply chain (Gupta and Palsule-Desai, 2011) and green supply chains (Srivastava, 2007). Environmental aspects, besides financial aspects, are concerned the most. Therefore, the authors propose the hypothesis:

H6b: Reverse logistics has a positive impact on environmental performance

Increasingly, manufacturers realize that a production system should not be a one-way system; rather it is a two-way closed loop (Lai et al., 2013). In fact, in many instances, export processing enterprises need to handle returned products which can be resulted from damaged or defective shipments, incorrect delivery, overstocks, and customer return due to dissatisfaction. Adopting and implementing reverse logistics is an effective method to solve this situation (Lai et al., 2013). On that basis, the authors propose the following hypothesis:

H6c: Reverse logistics has a positive effect on export performance.

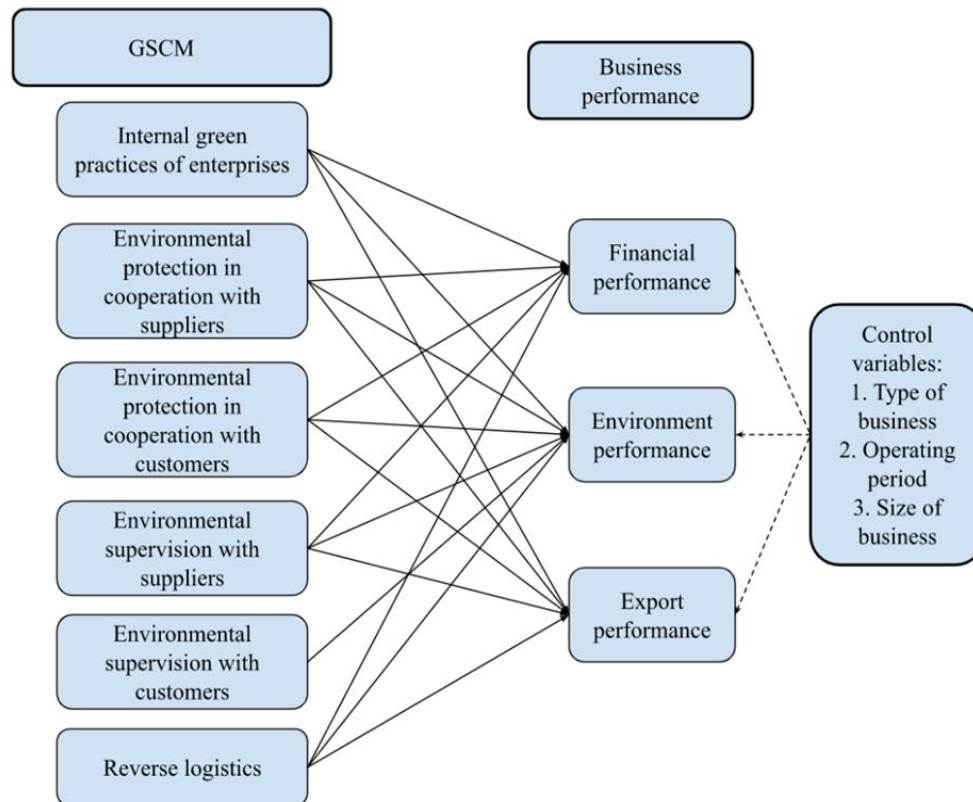

Figure 1. Proposed research model

Source: Authors' synthesis

3. Method

3.1. Research process

To achieve the research objectives, the authors use both qualitative and quantitative research methods. For qualitative research, the authors synthesize and analyze available data from reliable sources to clarify information related to the topic of green supply chain management within textile enterprises and transfer it into a relationship with business performance. Next, the quantitative research step is executed through SPSS 20 and AMOS 20 software, including assessing the reliability of the official scale through Cronbach's Alpha coefficient, performing exploratory factor analysis (EFA) and confirmatory factor analysis (CFA). When the CFA results have satisfied all the conditions, the research team continues to deploy the linear structural model (SEM) to determine the influencing factors and the influence level of each factor. In addition, the authors also used one-way analysis of variance (One-Way ANOVA) to study whether there is a difference in business performance by business characteristics.

3.2. Official sample selection

This study uses the random sampling method. The list of enterprises participating in the survey is randomly drawn from the overall study of textile enterprises across the country.

3.3. Data collection

The study was conducted on 235 textile and garment enterprises of Vietnam. We conducted a survey of Vietnamese textile businesses from August 2022 to February 2023. After 6 months of collecting data via email and through direct interviews we collected 286 questionnaires. However, after the process of data entry and elimination of the inadequate responses, only 235 answers were qualified to be analyzed. The questionnaire was developed based on the studies of Tran Thi Thuy Hang (2021), Laari et al (2016), Yang et al (2013), Green et al (2012a), Flynn (2010), Zhu (2008), Vachon & Klassen (2006), Akyol & Akehurst (2003), Zou, Taylor & Osland (1998), which focus on assessing the impact of green supply chain management on business performance. Specifically, the survey consists of three parts: general business information, questions concerning green supply chain management and questions relating to business performance. The second and third part of the questionnaire (about green supply chain management and business performance) are based on two different five-point Likert scales, which are briefly explained at the beginning of each part.

4. Results

The reliability analysis results using Cronbach's Alpha coefficient and Corrected Item-Total Correlation are presented in Table 1. If the testing results of the components on the scale have the Cronbach's Alpha > 0.6 and the Corrected Item-Total Correlation > 0.3, the scale has sufficient reliability to perform the next testing steps (Nunnally and Bernstein, 1994). As the results of Table 1 show, there are 49 out of 51 variables satisfying the preceding conditions.

Table 1. Cronbach's Alpha Test

Factor	Number of variables		Cronbach's Alpha
	Before testing	After testing	After
Internal green practices of business	13	13	0.992
Environmental protection in cooperation with suppliers	3	3	0.765
Environmental protection in cooperation with customers	4	3	0.775
Environmental supervision from suppliers	4	4	0.875
Environmental supervision from customers	5	5	0.857
Reverse logistics	4	4	0.803
Financial performance	7	6	0.882
Environmental performance	4	4	0.899
Export performance	7	7	0.906

Source: Result from SPSS 20

Exploratory Factor Analysis (EFA)

Table 2. KMO and Bartlett's Test (2nd time)

KMO and Bartlett's Test		
Kaiser-Meyer-Olkin Measure of Sampling Adequacy		0.857
Bartlett's Test of Sphericity	Approx. Chi-Square	6887.883
	df	1128
	Sig.	0.000

Source: Result from SPSS 20

After removing unsuitable variables, the results of the second KMO test gave a KMO value of $0.857 > 0.5$ and Bartlett's test with $\text{Sig.} = 0.000 < 0.05$; showing a high level of significance. In addition, the Total Variance Explained is $59.559\% > 50\%$ and the eigenvalues of the factors are all > 1 , so it is appropriate to use Exploratory Factor Analysis. Apparently, these 9 extracted factors have condensed 59.559% and lost 40.441% of the observed variables.

Confirmatory Factor Analysis - CFA

$\text{CMIN/DF} = 1,511 (< 3)$; TLI, CFI respectively receive the values 0.908 and 0.915 , satisfying the condition greater than 0.9 ; $\text{RMSEA} = 0.047 (< 0.08)$ is appropriate. Therefore, the model is compatible with the research data.

All scales have composite reliability higher than 0.7 ; Specifically, it ranges from 0.778 to 0.933 and the Average variance extracted (AVE) is also higher than 0.5 . Therefore, the scales are generally reliable.

The analysis results also show that all the Standardized and Unstandardized Coefficients of the scale are higher than 0.5 ; at the same time, the AVE values are also higher than 0.5 as suggested by Gerbing & Anderson (1988) and Fornell & Larcker (1981), so it can be concluded that the factors have convergent validity.

The discriminant validity test results show that all p -values are less than 0.05 . Therefore, it can be asserted that the correlation coefficient between the pairs of factors is different from 1 at 95% reliability level. On the other hand, the AVE of each factor is larger than the square of the correlation coefficients between that factor and the others. Therefore, the author concludes that the scales have discriminant validity.

Figure 2. Confirmatory Factor Analysis Model

Source: Result from AMOS 20

After analyzing the Structural Equation Modeling SEM, the analysis results show that the Chi-square = 1587,038; CMIN/DF = 1,513 (< 3); CFI = 0.914 (> 0.9); TLI = 0.908 (> 0.9) and RMSEA = 0.047 (< 0.08). These figures all satisfy the conditions, so it can be concluded that the measurement model is suitable for the market data.

Figure 3. SEM Result

Source: Result from AMOS 20

Table 3. SEM Result

Hypothesis	Correlation between factors		Unstandardized Coefficient	Std. Error of the Estimate (S.E.)	Critical Value (C.R.)	P_value	Standardized Coefficient

The SEM analysis results show that:

- In the relationship with Financial performance: Environmental protection in cooperation with customers with standardized coefficient of 0.408 has a stronger influence on Financial performance than Environmental protection in cooperation with suppliers does (standardized coefficient = 0.383).

- In the relationship with Environmental performance: Environmental protection in cooperation with suppliers has the strongest influence with the standardized coefficient of 0.387; followed by Internal green practices of business (0.266); Environmental protection in cooperation with customers (0.195); Environmental supervision from customers (0.171) and finally Reverse Logistics (0.161).

- In the relationship with Export performance: Environmental protection in cooperation with customers has the standardized coefficient of 0.299, which has a stronger influence than Internal green practices of business (0.270) and Environmental protection in cooperation with suppliers (0.262).

In summary, the test results demonstrate that the research model is highly compatible with the research data of the textiles sector in Vietnam with 10 accepted hypotheses.

Table 4. Result of hypothesis testing

Hypothesis		Result
Green supply chain management and Financial performance		
H1a	Internal green practices of business has positive impact on Financial performance	Not accepted
H2a	Environmental protection in cooperation with suppliers has positive impact on Financial performance	Accepted
H3a	Environmental protection in cooperation with customers has positive impact on Financial performance	Accepted
H4a	Environmental supervision from suppliers has positive impact on Financial performance	Not accepted
H6a	Reverse logistics has positive impact on Financial performance	Not accepted
Green supply chain management and Environmental performance		
H1b	Internal green practices of business has positive impact on Environmental performance	Accepted
H2b	Environmental protection in cooperation with suppliers has positive impact on Environmental performance	Accepted
H3b	Environmental protection in cooperation with customers has positive impact on Environmental performance	Accepted
H4b	Environmental supervision from suppliers has positive impact on Environmental performance	Not accepted
H5b	Environmental supervision from customers has positive impact on Environmental performance	Accepted
H6b	Reverse logistics has positive impact on Environmental performance	Accepted
Green supply chain management and Export performance		
H1c	Internal green practices of business has positive impact on Export performance	Accepted

5. Discussions and Conclusions

On the basis of research model and collected data from 235 surveyed enterprises, the authors draw some conclusions on the hypotheses about the impact of green supply chain management on business performance:

Firstly, in terms of environmental performance, the results show that most green supply chain management practices have a positive impact on environmental performance, except for Environmental supervision from suppliers which does not create a significant direct impact. The factor having the strongest impact on environmental performance is Environmental protection in cooperation with suppliers, with the standardized coefficient of 0.387.

Secondly, in terms of financial performance, the research results also indicate that Environmental protection in cooperation with customers have stronger influence on financial performance than Environmental protection in cooperation with suppliers, while Internal green practices of business, Environmental supervision from suppliers and Reverse logistics do not have direct impact.

Thirdly, in terms of export performance, the results show that there is a direct and positive impact of Internal green practices of business, Environmental protection in cooperation with suppliers and customers on export performance. Specifically, Environmental protection in cooperation with customers with the standardized coefficient of 0.299 has the strongest influence.

Finally, the results of testing the difference in business performance by enterprise characteristics point out that the larger the enterprise size is, the higher environmental performance and export performance are; the longer business's operating time is, the better the financial and environmental performance are; however, distinct types of business ownership make no difference in business performance.

Recommendations

The study has focused on examining the relationship between green supply chain management and the business performance of enterprises in the Vietnamese textile industry. Although the statistics and results are objective due to data limitations, through the research results, the authors are able to make several conclusions about the impact of green supply chain management on the business performance of Vietnamese textile enterprises and thereby suggest some solutions to enhance green supply chain management practices.

Analyzing the estimated results from the model has helped the authors bring up with some specific results:

First, most green supply chain management practices have a positive impact on environmental performance, except for the Environmental supervision in cooperation with suppliers practice which does not have a significant direct impact. In which, the factor showing the strongest impact on environmental performance is the Environmental protection in cooperation with suppliers. Through suppliers' sharings about experiences, lessons about innovation in improving technology, production and distribution process in an

environmentally friendly way, businesses can exchange in order to help develop their environmental management capacity as well as to acquire and transform the knowledge learned from suppliers into intangible assets to apply to their businesses, thereby develop the environmental management ability of both sides.

Second, the implementation of green supply chain management in the textile industry in particular and the economy in general is essential and has a positive impact on financial performance. Implementing green supply chain management will help businesses increase the efficiency of environmental management, improve their competitiveness, representation and reputation, and thus improve their financial performance.

Third, there is a direct and positive impact of the Internal green practice of business, Environmental protection in cooperation with suppliers and customers factors on export performance. Textile enterprises can enhance their global competitive advantage, improve their export performance by conforming international environmental standards through enhancing the use of green materials, green production, minimizing the use of hazardous materials, chemicals and unsafe machinery.

In general, within the study area of Vietnam with domestic textile enterprises as researched targets, it is apparent that Environmental protection in cooperation with customers and suppliers is a comprehensive option due to the positive impact on all three aspects: financial, environmental and export. In addition, cooperation will generally bring better results than environmental supervision. The study also shows that businesses with different characteristics (size, operating period and ownership type) also have different effects on business performance.

The practice of GSCM needs to be carried out inclusively from the business itself and all stakeholders, as well as throughout the supply chain from the preparation of input materials to the product quality assurance before delivery. Since all activities in the textile supply chain are inherently linked to each other, it is not enough to apply only one or a few steps in the entire chain, but to perform well in all aspects of the supply chain and the enterprises to create a unified and complete overall connection. In order to do that, the major requirement is that each business needs to have a clear and correct awareness of the value that GSCM can provide, going beyond the benefits for the business itself is the contribution to the sustainable development of the domestic textile industry in particular and the overall national economy in general. Thereby, the research team proposes a number of solutions to enhance green supply chain management activities as follows:

For textile enterprises, it is crucial to be properly aware of the necessity and importance of implementing green supply chain management in the present situation; strengthen and improve the internal quality of individuals being in charge of green supply chain management. In addition, it is critical to promote cooperation and supervision from customers to understand the current requirements and forecast their needs in the future, as well as to connect and closely support suppliers to transform knowledge obtained from them into intangible assets to increase business performance.

For the Government, it is vital to develop preferential policies that promote enterprises to produce and use green materials and increase environmental tax on polluting materials. Along with that, it is necessary to strengthen support for enterprises to participate in research and transfer advanced technology in the textile sector for the purpose of sustainable development; Further, enhance the association with textile enterprises as well as supporting enterprises in the process of training managers and highly qualified experts.

Abstract

This paper shows the importance of environmental innovation on the circularity performance of each country that creates favorable conditions to help countries move towards the circular economy. Six measures are used to reflect environmental innovation, including the percentage of enterprises that invest in environmental innovation, the percentage of enterprises implementing environmental innovation activities, the number of ISO 14001 certificates, patents related to environmental innovation, the total R&D personnel and researchers, and the amount of green early-stage investments. We provide empirical evidence that innovation in environmental activities is crucial for an economy's circularity performance, especially in the long term. Environmental innovation is also an essential enable of circularity.

Keywords: *green innovation; circularity performance; economic circularity; European countries.*

1. Introduction

As humans continue to abuse and misuse natural resources, ecosystems worldwide are on the verge of collapse. The environment has already reached several tipping points, increasing the possibility that irreversible changes could occur in the future. There has been a growing recognition of the necessity to decouple social and economic development from the extraction of resources and waste disposal in recent decades. In the 21st century, one of the most challenging issues appears to be balancing economic growth among competing countries while raising the standard of living for a population projected to exceed 10 billion in the mid-century. The OECD (2012) reports that the sustainable development of global biodiversity cannot be compromised by a limited number of natural resources.

A circular economy is gaining traction because of the limitations of conventional economies. Business organizations, industrial organizations, and national agendas have been urged to place closed-loop thinking at the core of the "circular economy" (CE) (Preston, 2012). In recent years, CE has grown in importance as a study issue with the support of institutions like the UN and the EU (UNEP, 2014). However, there remains confusion over what changes need to be made and how they can be achieved (Schulte, 2013), even though

change is necessary for businesses and governments. Although "eco-innovation" (EI) is a critical factor in promoting change, the sustainability transition is seen as the primary driver of change. According to Carrillo et al. (2010), innovation can take various forms, including products, processes, marketing, and organizational benefits. Essentially, sustainability has been acknowledged by the European Commission as an integral component of achieving "environmental benefits," which include more efficient use and consumption of resources (EC, 2012) and more competitive business models and technologies (Al-Ajlani et al., 2021). In policy, transitioning to a circular economy has been referred to as a "catalyst" (Russo, 2018).

However, several researchers have examined the EI's significance to a CE rather than using methodologies that focus on the confluence of CE and EI (EIO, 2016). Innovation efforts should be coordinated with sustainable approaches to bring about a tech-economic paradigm shift (Mirata & Emtairah, 2005). EI can be used to facilitate the changes needed to deploy and reinforce the CE framework in its current form. It is still unclear, however, how EI will facilitate a pro-CE transition. A relationship between environmental innovation and circularity is explored to contribute to the debate regarding sustainable transition. It is the first study to provide a theoretical basis for examining the effect of countries' economic inclusion on circularity performance. The six factors that measure environmental innovation include the percentage of investments in environmental innovations, the percentage of enterprises implementing environmental innovations, the number of ISO 14001 certifications, the number of patents related to green innovation, the number of researchers and R&D personnel, and the total amount invested in companies at their inception. This article uses several measures to assess the efficiency of the circularity process. Circularity can be measured by the amount of waste generated, patents relating to circularity, circular materials used, recycling rate, biowaste recycling, and e-waste recycling. Combining various techniques and practical approaches, we analyze a sample of European countries from 2012 to 2019. Because no other area offers thorough metrics of circularity, this database was selected. The other measurements, which are relatively dated and unable to reflect the diversity of circularity, do not accurately depict circularity performance. After continually analyzing the cross-sectional dependence and stationarity, we employ the PCSE (panel-corrected standard errors) model in the following section to study the relationship between EI and circularity. Our findings are further confirmed by utilizing the FGLS (feasible generalized least squares) model to account for heteroscedasticity. Additionally, the ARDL (autoregressive distributed lag) approach is linked with the PMG (pooled mean groups) estimator to assess both short- and long-term effects. Both time-fixed impacts and country-specific effects can be addressed with PMG-ARDL.

An integrated, dynamic corporate model and pro-CE governmental policy will promote this transformation. Therefore, research with a broader scope seems essential to understanding its dynamics. The remaining sections are organized in the manner shown below. In Section 2, a review of the literature is done before the creation of hypotheses. A model, data, and estimating strategy analysis is done in Section 3. The following section includes a discussion in addition to the empirical findings. The final stage will examine research findings and their policy implications.

2. Literature review: Circular economy and eco-innovation

2.1. A brief review of the link

It seems impossible to obtain CE on its own, given the link between CE and EI that is intuitively obvious. However, the specifics of this have yet to be determined. In actuality, not all aspects of CE require innovation, nor are all aspects of CE related to an EI. There will undoubtedly be some overlap between the two, however. To decide which improvements will be most suitable for CE models and what technological modifications are required to create a CE, it is crucial to have a deeper grasp of these two ideas.

Since Joseph Schumpeter's seminal writings (1934), innovation has been recognized as more than newness (Schumpeter, 1934). Instead, this is what happens when production variables are combined with fresh ideas. Adapting to a particular context, such as integrating a brilliant idea into an unconventional economic or institutional situation, requires more than technical competence (Fagerberg et al., 2010). To put it another way, innovation does not just refer to improvements in science and technology. This viewpoint has led to the conclusion that innovation is not a natural outcome of increasing research and development, nor is it passively impacted by market factors (Caraça et al., 2009).

Innovation does not necessarily result in more beneficial outcomes for welfare or sustainability: Sometimes, tackling new issues does not lead to improved outcomes (Soete, 2013). Technological viability is not necessarily a guarantee of morally righteous conduct or environmental sustainability (UNEP, 2011). In retrospect, the mass production methods developed in the 20th century that were extraction-based and carbon-intensive create essential issues. This may result in some innovative concept revisions or some intellectual property damage. A crucial transitional element is altering "how we innovate." (Schot & Steinmueller, 2018). A transition is a complicated, dynamic process in which numerous people take part, specific actions are taken, and ongoing activities last for a considerable time. During this time, new organizational structures, products, and business models replace or supplement the existing ones characterized by an interconnected series of technological and non-technology advancements. As the environment became a significant policy concern, innovation ideas began to focus on transitional issues and broader societal concerns (Boons et al., 2013; Rennings, 2000). During the industrial era, there was no scope for this growing 'pro-environment' innovation agenda (Freeman & Soete, 1997).

As the environmental perspective has entered and spread, there have been specific linguistic changes in innovation studies. As a dynamic process encompassing several activities and changing over history, the idea of innovation has become more and more prevalent (Castellacci et al., 2005). In addition to the "high-tech" sector's suppliers' research and development, social and cultural elements influenced its development. Several studies on transition and sustainable development have benefited research on innovation (Smith et al., 2010). Studies on sustainability and transition focus on science and technology as a socially embedded process; knowledge and mental models are connected depending on user skills, institutions/regulations, and infrastructure, and consumer expectations are shaped (Markard et al., 2012).

There is no agreement on how sustainability transition techniques should be implemented. Numerous theoretical methods, including those based on evolutionary economics and niche management, are helpful and coexist with a variety of opinions (Kemp et al., 1998) and technology innovation systems or approaches that utilize multiple levels of analysis to understand sociotechnical changes (Geels, 2011) or innovative ecosystems are some examples. Even though creativity in terminology can be viewed as an indication of the concept of restlessness, the "Proliferation of labels" may hinder development in a field (Barney, 2017). "Environmental innovation refers to innovation that benefits the environment (van den Bergh et al., 2011). The notion of "sustainable innovation" indicates an innovation that considers ecological, economic, and social factors, thus taking into account spatial, temporal, and cultural contexts, in addition to product and process innovations (Clark & Charter, 2007) as organizational models. According to Cuerva et al. (2014), "green innovation" involves developing, improving, or creating new products or processes that promote environmental sustainability. In recent years, "Business model innovation" has also gained traction within the semantic field. In this case, business model innovation enhances the organization's ability to produce, deliver, and capture value to maximize its contribution to society (Bocken et al., 2014).

Given that (E)recent's expansion of its purview beyond its initial emphasis on "end of pipe" technologies, Economic performance today is described as creating a business climate that does not impede sustainable development (i.e., economically, ecologically, and socially sustainable). The European Commission (EC) describes it more favorably as a strategy for accomplishing or striving for actual advancement in the pursuit of sustainable growth, which includes minimizing environmental damage, enhancing environmental resilience, or making more responsible use of natural resources (EC, 2011a). EI is crucial to sustainability and can promote enhanced competitiveness without negatively affecting society and the environment (OECD, 2009). (EC, 2011b). Despite some irreducible variability, there may not be many worthwhile attempts to simplify and consolidate in this case. Following the choice in the article, the word "environmental innovation" will be used to refer to a standardized and inclusive phrase for all ecologically conscious innovations. Innovations that consider the environment positively impact the environment or address environmental issues. We use EI and CE together as the fulcrum of establishing a new transparent, coherent paradigm for tech-economic development in light of the revamping of studies on "transformative innovation." (Schot & Steinmueller, 2018).

2.2. Refocusing and untangling the concept of eco-innovation

Understanding EI and its dimensions is necessary for policy-making, entrepreneurship, and academic research. An innovation that prevents, mitigates, or recovers environmental damage can be defined as a broad, applicable, operational definition. According to Barbieri et al. (2022) and Veefkind et al. (2012), a definition of this type must include: (i) Environmentally friendly innovation (e.g., green innovation); (ii) Creating clean and efficient results for the market (e.g., environmental innovation); (iii) Socially responsible and lasting benefits (e.g., sustainable innovation); (iv) Change of the whole business model (i.e., innovation of a sustainable business model).

This definition offers a strong foundation for finding other sides of the argument and providing an analysis of EI from other angles. EI is studied from three different perspectives: innovations (targets), mechanisms of change (mechanisms), and overall effects, in accordance with the innovation recommendations in the Oslo Manual (OECD, 2009) and the existing EI typologies (impacts). EI can be defined as an innovation that: a) has a positive impact on the environment; b) provides cost-efficiencies, market enhancements, or regulatory considerations while preventing natural capital damage; c) creates new or enhanced products, services, technologies, organizational, or marketing strategies; d) reflects radical change or incremental growth; and e) involves single or multiple actors. This definition puts this discussion into operational terms.

2.3. Changing to a sustainable approach through CE-friendly approaches: a family of CE-friendly concepts

With the signature of the inaugural accord by 175 governments (including the US and China as the founding signatories), the European Union, and 174 countries following the Paris Climate Conference 21, a high degree of expectation has been generated (UNFCCC, 2016). Diverse entities compete in a dynamically dynamic global market, but their interests are not aligned as they deal with the effects of ongoing environmental degradation while trying to stay competitive. The new methods would emphasize prolonging the useful lives of materials, reusing them, remanufacturing them, and recycling them while separating resource consumption from development (UNEP, 2011). While it is increasingly recognized that change is necessary, the specific pathway of transition is much less clearly defined. Literature has proposed several approaches to frame the CE discussion, which has shaped our understanding of it today.

CE is based on several concepts that are not new. Utilizing waste materials from animals (e.g., pelts, blood, and bones) for clothing, shelter, weapons, and jewelry dates back to the Neolithic period (Desrochers, 2000). Similar to today, cooperative arrangements between manufacturers and consumers were already in use during the 19th century through the exchange of byproducts in exchange for services (Desrochers, 2000, 2002). It emerged during the latter half of the twentieth century, along with concerns about resource exhaustion on a planetary scale that emphasized the necessity of finding a new equilibrium within the "System of ecological cyclicality"; Georgescu-Roegen's (1986) view of economic complexity as a function of entropy. A whole chapter by Pearce & Turner (1989) argues that environmental values are economically viable in the light of Boulding and Georgescu-claims Roegen's that natural systems are capable of producing garbage. However, they absorb and recycle it as opposed to conventional open-ended economies. This is the first discussion of CE as a label. The authors make a case for circular material flow in the economy that man has created. A loop system that replicates nature will result in fewer fresh inputs and slower depletion of the environment's resources and trash (by sourcing materials and eliminating waste). Instead of merely trashing the environment or producing things that will become outdated over time, resource use should create new resources that can be recycled.

Frosch & Gallopoulos (1989) popularized the concept of CE in industrial ecology, particularly in the US (1998). The literature on industrial ecology proposes that organizations adopt natural systems' tactical approaches. The idea of "material symbiosis," which uses waste byproducts to make materials for other processes and enterprises, is a crucial part of the theory (Kiefer et al., 2019). Numerous European institutions have adopted the idea of industrial symbiosis, which is growing in popularity. This essay's primary focus is identifying a "systems integration" strategy whereby businesses exchange byproducts and complete their material cycles. This strategy has been seen as an essential part of implementing CE.

The "Cradle to Cradle" method, one of the cornerstones of CE, highlights the tight production requirements that must be transformed into a self-feeding services nexus that collaborates to produce jobs, save resources, and cut waste (W. R. Stahel & Reday-Mulvey, 1981). Eventually, it was realized that services have the potential to revitalize the economy. In 2010 and 2013, Stahel (2010, 2013) claimed that by offering "services," manufacturers might extend the lifespan of their products while using fewer fresh inputs. This benefits both producers (who can continue to control their assets) and consumers (who only pay for the advantages).

In addition, several concepts that follow the 3Rs of "reduce, reuse, and recycle" are discussed, as well as the conception of a closed loop, such as zero emissions or a system where everything is used and cycles of nature are performed (Pauli, 2010). McDonough & Braungart (2010) have furthered the "cradle to cradle" concept; and the concept of "zero waste." A concept that emerged from multiple ideas and schools of thought, it has many applications today. As the CEs have different meanings and responsibilities for different stakeholder groups, all of these contributions should be considered in their respective contexts (EIO, 2016).

2.4. The formal concept of circular economy

To "bring circular economy theory into action through industry sectors, major economic areas, and urban demonstration projects," two batches of circular economy pilot projects were carried out between 2005 and 2007. The Circular Economy Promotion Law was passed in 2008 and came into effect in 2009 in order to promote energy efficiency, sustainable development, and environmental protection (Geng et al., 2012). A key message of the 12th Five-Year Plan (2011E15) was eco-industrial importance.

The EU unveiled a circular economy action plan to enter the western policy sphere in 2015 (EC, 2015). The CE study has received significant support from think tanks and private organizations in recent years, notably the Ellen MacArthur Foundation (EMF). This momentum appears to be influenced by many factors. It has been noted that the CE concept offers both financial advantages and commercial solutions simultaneously, making it more practical and real-world than other environmental conservation strategies (Sauvé et al., 2016). Finland, France, the Netherlands, Spain, and Sweden are a few nations that have emphasized its potential to increase trade balance, decrease CO₂ generation, and create jobs. According to the Groupo Interministerial Economia Circular from 2017, Portugal has also

started holding discussions over its CE Action Plan for 2017 through 2020. Along with considering the idea as a tool for enacting policy, the EU Circular Economy Action Plan's (EC, 2017) financial prospects have also been considered.

As a result, the CE cannot be considered a consensus concept, nor can its definition be agreed upon (Kirchherr et al., 2017). Many other definitions have been offered by organizations, including the United Nations, non-governmental organizations, and academic institutions. While the definitions highlight specific components that describe what the CE entails, they also highlight a set of fundamental elements: i) minimizing waste and utilizing renewable resources efficiently; ii) extending the life cycle and reconceptualizing systems; (repairing, reconditioning, and remanufacturing; procuring and outsourcing; and innovating on business and procurement models); and iii) valorizing output reductions and waste (recycling, recovering, and valuing byproducts and waste).

In an attempt to extend Freeman & Soete's (1997) work, de Jesus et al. (2018) propose the notion of clean convergence, i.e., convergence between technological and social subsystems capable of overcoming the problems associated with Fordist, depletion-prone, carbon-intensive times. CE is the most durable, self-reinforcing, and enduring among all positive congruences.

In order to understand the level of granularity of CE implementation, three levels of analysis are required (Ghisellini et al., 2016). An individual actor may be targeted by CE at a micro level, especially a company (Zhu et al., 2010). Examples include initiatives to limit resource usage, the use of labels, eco-friendly consumer patterns, and environmentally friendly production techniques. On a meso level, it concerns actor interactions, particularly between businesses. Examples include the management of green supply chains and industrial symbiosis (Zhu et al., 2010). On a national or international scale, CE has typically been associated with legislation, regulatory impact evaluations, zero-waste policies, and communities that prioritize recycling.

The following are some definitions of CE in this context: a) Towards "clean congruence" through the direction of new institutional arrangements balancing environmental concerns with socioeconomic performance while simultaneously promoting technological development that is independent of finite resources; b) the development of multi-level frameworks (microscopic, mesoscale, and macroscale) for reshaping and reorienting resilience and sustainability in production and business models; and c) a concept.

2.5. The circular economy and eco-innovation: connecting the two

Cheap resources drove the 20th century for widening markets, and the early 21st century has brought heightened volatility in prices and uncertainty in the geoeconomic arena (Barney, 2000). Despite recycling being considered essential, waste production is still relatively unchecked (WWF, 2014). By 2050, global consumption is expected to triple due to a dramatic rise in consumption over the last two centuries (van Langen et al., 2021). Consumers are growing more conscious of climate change, and environmental regulations are tightening. A closed-loop economic model that encourages innovation along the entire

value chain can be an alternate strategy to reduce the waste of resources and energy in a competitive, dynamic, but limited environment, as advocated by UNEP (2006, 2011, 2012).

Since the Lisbon Strategy was announced in 2000, the EU has assumed a global leadership position in creating and implementing sustainable economies and communities. The EC has recently created several flagship programs, and action plans to support the transition to sustainability, including EI (EC, 2011a); and efficiency in resource use (EC, 2011c). The Circular Economy Action Plan confirms that the EU is committed to creating a circular economy and highlights the direct connection between CE and innovation and EI (EC, 2017). This argument says that the CE depends on methodically implementing eco-innovation, which encompasses all participants in value and supply chains (EC, 2016).

It is a dynamic company that constantly rewrites overlaps between diverse activities to change manufacturing processes and consumption patterns (EMF, 2013, 2012). Due to the advent of new technology as well as new business models and structures, Tregner-Mlinaric & Repo (2014) identified EI as a crucial tool for achieving this. Consequently, it is possible to investigate the EI-CE linkages, which is the study's main objective.

Even if the relationships between the two concepts are intricate, there are still numerous parallels. Both have ambiguous borders that cover many related words. Even though it seems intuitively evident that they are and that CE cannot be attained without EI, it is yet unknown how CE and EI are connected. EI affects more than just the CE; it can also have an impact on the CE in other contexts. Even though there is an undeniable connection between the two, a more in-depth examination may make use of both the micro and macro levels of CE (vertical axis) as well as all the previously described factors (horizontal axis) to provide better insight. The horizontal axis of the picture depicts the dimensions of each level of CE in relation to the EI dimensions. The subsequent literature study distills useful insights in addition to offering supporting data. Specific sorts of change must be implemented once a closed-loop, production-utilization congruence has been reached through a deeper comprehension of the overlap between CE and the EI. These self-reinforcing tendencies can be tracked and mapped by policy and decision-makers in their search for CE transition strategies. The concept of "clean congruence" resolves discrepancies between ecological and economic sustainability from several angles in the context of a new (green, innovative) techno-economic paradigm.

3. Method

A model explaining the nexus between environmental innovation performance (EPI) and circularity performance (CIR) is as follows:

$$CIR_{it} = \beta_0 + \beta_1 EPI_{i,t} + \beta_2 EG_{i,t} + \beta_3 TS_{i,t} + \beta_4 FDI_{i,t} + \beta_5 IND_{i,t} + \beta_6 EPI_{i,t} + \beta_7 NR_{i,t} + \beta_8 DM_{i,t} + \varphi_t + \omega_i + \varepsilon_{ijt}, \quad (1)$$

where i and t respectively represent country i and year t . φ_t and ω_i are added into the model to capture the country and year-fixed effects, and ε_{ijt} is the error term.

Circularity performance (CIR)

To measure the performance of circularity in European countries, we use six different measures, including the proportion of the municipal waste generated per capita (kilograms) is measured by the CIR_MW; the number of patents related to recycling and secondary raw materials (*CIR_PA*); circular material usage (*CIR_MA*) calculated as the circular material use rate (%); CIR_RW performance based on all waste excluding major mineral waste (%); the recycling rate of biowaste (*CIR_RB*); CIR_RE measures the recycling rate of e-waste (%). Statistics are taken from Eurostat (2012-2019).

Key explanatory variable:

Following Al-Ajlani et al. (2021), Six metrics are used to assess the effectiveness of EI in European nations, including the proportion of businesses making EI investments (% of firms surveyed); the proportion of businesses engaging in EI activities (such as implementing resource efficiency actions, sustainable products, or ISO 14001 certifications) based on the share of certified firms among firms surveyed; the proportion of businesses with 14001 registrations; and the number of businesses with EI investments (per min population). We investigate the effects of total investments in R&D employees and researchers (EI RD), evaluated as a share of total employment, and the total value of green early-stage investments per capita (EI GREEN), to further illuminate this connection. The OECD Statistics from 2011 to 2019 are the sources for these variables.

Control variables:

To determine the control variables, we used literature-based empirical studies, especially Bu et al. (2019) and Nham & Ha (2022). We have taken economic growth (*EG*), trade share (*TS*), industrialization level (*IND*), and democratization level (*DM*) as explanatory variables. We also use the percentage of net FDI inflows in our theoretical model. Following Le & Nguyen (2019), we consider the effects of natural rents (*NR*), while a level of democratization (*DM*) is also added. These variables are taken from World Development Indicators (WDI). Information and statistics about all variables are provided in Table 1. The final sample contains cleaning data from 18 countries during the 2012-2020 period. As shown in Table 2, all variables that suggest a positive correlation between Municipal waste per capita and EI are included in the correlation matrix.

Notably, the project's short-term and long-term effects are considered. Accordingly, Pesaran & Smith (1995) developed the ARDL method. Considering the potential presence of endogeneity in this model, a pool means group (PMG) is used to account for causal relationships between variables and heteroscedasticity across countries. To begin estimating the relationship between the two variables, we use the Kao (1999), Pedroni (2004), and Westerlund (2005) 's tests. In Table 4, we find that economic complexity, product proximity, and circularity co-integrated over the long run.

To shed light on the distinct effects of environmental innovation, we concentrate on nonlinear impacts of economic complexity and product proximity on circulation in the subsequent analysis.

Table 1. Description of Variables

Variable	Definition	Measure	Source	Obs	Mean	SD	Min	Max
CE_MW	Municipal waste per capita	Generation of municipal waste per capita (Kilograms per capita)	Eurostat	171	478.49	129.45	239.00	830.00
EI_ENTER	Enterprises with Environmental innovation	The percentage of enterprises implementing environmental innovation investment (% of surveyed firms)	OECD.Stat	162	77.60	36.21	0.00	155.00
EI_ACT	Environmental innovation activities	The percentage of enterprises implementing environmental innovation activities (e.g., implementation of resource efficiency actions, sustainable products, or ISO 14001 certificates) (% of surveyed firms)	OECD.Stat	162	94.09	32.91	38.00	171.00
EI_ISO	Enterprises with new 14001 registration	Number of ISO 14001 certificates (per min population)	OECD.Stat	162	93.31	46.77	0.00	168.00
EI_PATENT	Environmental innovation-related patents	Environmental innovation-related patents (per min population)	OECD.Stat	162	127.40	72.89	0.00	322.00
EI_RD	Investments in R&D personnel and researchers	Total R&D personnel and researchers (% of total employment)	OECD.Stat	162	113.98	60.47	25.00	226.00

Variable	Definition	Measure	Source	Obs	Mean	SD	Min	Max
EI_GREEN	Environmental early-stage investments	Total value of green early-stage investments (USD/capita)	OECD.Stat	162	105.91	114.01	0.00	422.00
EG	Economic growth	The real GDP per capita (constant 2010 US dollars).	WDI	171	36.93	27.75	1.02	111.15
TS	Trade share	The proportion of GDP.	WDI	171	1.29	0.70	0.55	4.08
FDI	Net inflow of foreign direct investment	The proportion of GDP.	WDI	171	0.04	0.27	-1.54	1.63
IND	Industrialization level	The value added to GDP.	WDI	171	0.23	0.06	0.11	0.37
EPI	Environmental performance index	The score is scaled between 0 and 100, where 0 and 100 mean worst and best performance, respectively.	YCELP	171	71.81	7.41	60.18	82.86
NR	Natural rents	The share of the sum of coal rents, mineral rents, natural gas rents, and forest rents to GDP (%).	WDI	171	0.88	1.73	0.01	10.97
DM	Level of democratization	The index of democratization	FSSDA	171	1.60	0.49	1.00	2.00

4. Results

4.1. Environmental innovation and circularity

The effect of environmental innovation-related activities on the performance of circularity security is shown in Table 5 (CIR). We primarily concentrate on examining the association between variables using the PCSE estimate and FGLS estimate. When assessing how EI-related actions (EI ENTER, EI ACT, EI ISO, EI PATENT, EI RD, EI GREEN) would affect the amount of municipal garbage generated per person (CE MW). The FGLS and PCSE calculations come to identical findings in Panels A and B. The findings show that all effects on municipal trash per capita (CE MW) of EI ENTER, EI ACT, EI ISO, and EI PATENT are at a 1% significant and negative level. EI ENTER, EI ACT, EI ISO, and EI PATENT, specifically, have coefficients of -0.95, -1.34, -1.77, and -0.53, respectively. As a result, municipal waste per capita will also decrease due to increased environmental innovation-related activities, such as the percentage of investments in enterprises implementing EI, the percentage of enterprises implementing EI activities, the share of certified firms among surveyed firms, and the number of EI-related patents. Environmental innovation will also lead to an improvement in the quality of the environment. Our research supports this. Similarly, Rodríguez-Espíndola et al. (2022) also provide empirical evidence on the link between EI and circularity performance. Suchek et al. (2021) also provides systematic literature on this association.

4.2. Robustness checks

4.2.1. Short-run and long-run effect: Dynamic fixed effect ARDL model

We perform robustness testing in a later stage to confirm our earlier conclusions. First, we make a distinction between the impact of environmental innovation on the long- and short-term performance of circularity security. Table 6 provides an overview of the outcomes. The short-term results show that only EI ISO has a statistically significant impact on EC MW, suggesting that raising the proportion of 14001 (EI ISO) registered firms will reduce municipal trash per capita. The other EI variables' coefficients lack statistical significance, indicating that the EI ENTER, EI ACT, EI PATENT, EI RD, and EI GREEN, municipal trash per capita, are not immediately apparent from empirical data. The long-term

effects of businesses with environmental innovation, businesses with environmental innovation activities, businesses with new 14001 registration, businesses with patents related to environmental innovation, businesses with investments in R&D personnel and researchers, and businesses with investments in early-stage environmental investments are statistically significant at 5% and 1% and positive, with the coefficients being 31.69, 0.85, 4.52, 0.52, 1.45, and 0.12, respectively. The findings point to a positive impact of environmental innovation, but this benefit is more likely to last over time.

Note: PMG-ARDL is employed.

4.2.2. Endogeneity control: Two-step GMM

Finally, endogeneity may result from circularity and environmental innovation occurring at the same time. We utilized a two-step GMM estimate depicted in Table 7 to overcome this issue, following Nham & Ha (2022). In Panel A, municipal garbage generated per person is statistically influenced by EI ENTER and EI ACT. In Panel B, we employ the squared term of EI, and the results show that, with the exception of the impact of all EI on circulation patents, which is statistically significant at 10% and positive, all EI measures have a negative influence on circularity. Additionally, because the squared term of environmental innovation's negative correlation with circulation patents is statistically significant, the negative effects of environmental innovation are reported. However, we also uncover evidence supporting the positive impacts of product proximity.

5. Conclusions

We are the first to distinguish clearly between the significance of environmental innovation on each nation's performance in terms of circularity. Our study is anticipated to evaluate the enablers of circularity in depth by using a variety of variables to capture diverse circularity difficulties. This study demonstrates how environmental innovation has uneven, nonlinear consequences on circularity. We do, however, offer empirical proof that innovative efforts, including the environment, are crucial for improving a nation's performance in terms of circularity, particularly over the long term. Another crucial enabler of circularity is environmental innovation.

According to the facts discussed above, environmental innovation is more practical for stabilizing the circulating economy and assisting in limiting emissions to the environment from an economic standpoint. Therefore, increasing the quantity and quality of businesses investing in environmental innovation activities should be one of the top economic priorities. The government should also develop sophisticated capabilities to promote economic advancements. A more successful development strategy is to make it easier for businesses to invest in and develop green spaces.

ASSESSMENT OF AGRICULTURAL LAND QUALITY IN THE BUFFER ZONE OF TAM DAO NATIONAL PARK

PhD Student. Ta Ngoc Long
tangoelong1982@gmail.com

Prof. Dr. Nguyen The Dang
nthedang@gmail.com

Thai Nguyen University of Agriculture and Forestry, Thai Nguyen, Vietnam

Abstract

The conflict between forest and land conservation of Tam Dao National Park and the need for land use of people living in the buffer zone is increasingly severe. Therefore, it is necessary to determine the quality and potential of agricultural land to orient sustainable development for people in the buffer zone. With that requirement, from 2021 to 2022, a study on sustainable use of agricultural land in the buffer zone of Tam Dao National Park was carried out. The method of conducting this research is to survey and analyze the current situation of the study area according to current regulations. Research results show that: The entire land of Tam Dao district belongs to the buffer zone of Tam Dao National Park and includes 5 soil groups with 9 soil types divided into 2 subregions 1 and 2. On the basis of overlapping 6 single-use maps: soil type map, soil thickness map, slope map, climate sub-region map, irrigation regime map and soil fertility map, identified the buffer zone of Tam Dao National Park in Tam Dao district with 51 quality units of agricultural and forestry land. Out of a total of 20,378.04 hectares of land in the buffer zone of Tam Dao national park in Tam Dao district, there are 6,192.22 hectares of high-quality land, accounting for 30.39%; the average quality land area reached 3,928.97 ha, accounting for 19.28% and the area of low quality land was very high, up to 10,256.85 ha, accounting for 50.33 %.

Keywords: *National park buffer zone, Land unit map; Soil quality; Tam Dao district*

1. Introduction

Tam Dao National Park is a national park of Vietnam, located entirely on the Tam Dao mountain range, a large mountain range over 80 km long, 10-15 km wide running in the Northwest - Southeast direction. Tam Dao National Park is adjacent to the districts of the three provinces of Vinh Phuc, Thai Nguyen and Tuyen Quang. The entire area of Tam Dao district of Vinh Phuc province lies within the buffer zone of Tam Dao National Park.

The living source of the majority of people in Tam Dao district mainly depends on Tam Dao National Park, so the pressure on natural resources in the region is very high. The conflict between forest and land conservation of the National Park and the need for land use of people living in the buffer zone is increasingly severe.

To satisfy people's needs for food, agricultural production must go in two directions: Intensive farming to increase crops, increase crop productivity or expand agricultural land

area. Either way, investigating and researching land to master the land fund in both quantity and quality is essential.

Therefore, the correct assessment of the land use status of the buffer zone and the proposal of sustainable agricultural land use orientation is a reliable scientific and practical basis for the good exploitation of land resources on the one hand, on the other hand, to find the optimal solution to both preserve the National Park and improve the living standards of the people sustainably.

2. Method

2.1. Selecting research sites

On the basis of specific characteristics, the national park area occupies the majority in Tam Dao district, Vinh Phuc province and the objectives of the study, divided into two research subregions as follows:

- Subregion 1: It has the economic, cultural and political centers of the locality. Including 3 towns are Tam Dao, Hop Chau and Dai Dinh.

- Subregion 2: The remaining 6 communes of the buffer zone including Ho Son, Dao Tru, Minh Quang, Tam Quan, Yen Duong and Bo Ly.

2.2. Soil classification

On the basis of inheriting the results of the First survey to assess land quality and land potential in Vinh Phuc province in 2019, the topic will separate the Tam Dao district, then carry out a re-investigation through the survey route. Field observations on soil types, parent rock and landscape to synthesize soil type data for the whole district.

2.3. Building land unit map (soil quality unit)

Based on the characteristics of soil, topography, climate, water regime and land use characteristics, according to the requirements of Circular No. 60/2015/TT-BTNMT, a set of criteria for soil quality assessment has been determined, including: 6 groups of indicators: Soil type, topography, soil thickness, climate, water regime and soil fertility.

Using Microstation SE software to digitize and build simple maps including: Soil type map, slope map, soil thickness map, climate map, irrigation regime map, degree map soil fertility. Using ArcGIS 10.2 software in superimposing single-use maps (thematic maps) to build a unit map of soil quality of the buffer zone of Tam Dao national park.

3. Results

3.1. The results of determining criteria and hierarchical criteria to build a map of land units

To build a map of land units, the study was based on the following bases:

Based on the inheritance of the soil map and the results of soil quality assessment of Vinh Phuc province in 2019 along with the results of the survey and investigation on the characteristics of agricultural land types of Tam Dao district and with the results synthesize current documents on natural conditions (land, climate) of the district.

Based on the characteristics of soil, topography, climate, water regime, land use characteristics and the requirements in Circular No. 60/2015/TT-BTNMT, a set of criteria has been determined to build a map. Land unit map of the buffer zone of Tam Dao national park in Tam Dao district, Vinh Phuc province. Including 6 groups of indicators (*Table 01*).

Table 1. Result of decentralization of criteria for building a map of land units in the buffer zone of Tam Dao National Park

Indicators	Hierarchy	Symbol
1. Soil type (G)	Dystric Fluvisols (Pbc)	G1
	Gleyic Fluvisols (Pg)	G2
	Haplic Acrisols (B)	G3
	Umbric Gleysols (D)	G4
	Red yellow soil on acid magma rock (Fa)	G5
	Red-yellow soil changes due to wet rice cultivation (Fl)	G6
	Light yellow soil on sandstone (Fq)	G7
	Red and yellow soil on clay rock (Fs)	G8
	Red yellow humus soil on acidic magmatic rock (Ha)	G9
2. Slope (SL)	0 - <8°	SL1
	≥ 8 - <15°	SL2
	≥15 - <25°	SL3
	≥ 25°	SL4
3. Soil layer (D)	> 100 cm	D1
	≥ 50 - 100 cm	D2
	< 50 cm	D3
4. Climate (KH)	Amount of rain ≥ 2.500 mm (R3), Total temperature < 7,0000C (T1), dry month < 2 month	KH1
	Amount of rain 1,500 - < 2,500 mm (R1), Total temperature ≥ 7,000 - 8,000 ⁰ C (T2), dry month ≥ 2 - 3 month	KH2
5. Irrigation (I)	No waterlogging, watering due to rain	I1
	No waterlogging, semi-active irrigation	I2
	No waterlogging, active watering	I3
6. Fertility* (DP)	Low fertility	DP1
	Average fertility	DP2
	High fertility	DP3

Notes: * Including OM, N, P, K total; Density, pH, Mechanical Composition and CEC

3.2.1. Analysis results from target groups

3.2.1.1. Criteria for soil type

The data resulting from the construction of a map of agricultural land in the buffer zone of Tam Dao National Park (in Tam Dao district, Vinh Phuc province) at the scale of 1/25,000, has identified that the whole district has 5 groups of soil with 9 types of soil classified as: out in 2 subregions 1 and 2 (*Table 02*). In which, red yellow soil group on acid magma has the largest area with 2,640.03 ha in subregion 1 and 7,990.42 ha in subregion 2; group of red-yellow humus in the mountains is 2,129.59 ha, mainly in subregion 2 with 1,278.10 ha. Light yellow soil on sandstone is mainly concentrated in subregion 2; The alluvial soil group is only 66.06 ha and is concentrated in subregion 1.

Table 2. Area of land type in the buffer zone of Tam Dao national park by subregion

<i>Unit: ha</i>				
No	Soil type	Symbol	Sub-region 1	Sub-region 2
1	Dystric Fluvisols (Pbc)	G1	53.99	12.07
2	Gleyic Fluvisols (Pg)	G2	339.89	868.37
3	Haplic Acrisols (B)	G3	286.25	1,430.75
4	Umbric Gleysols (D)	G4	396.92	637.23
5	Red yellow soil on acid magma rock (Fa)	G5	2,640.03	7,990.42
6	Red-yellow soil changes due to wet rice cultivation (Fl)	G6	18.94	424.24
7	Light yellow soil on sandstone (Fq)	G7	121.10	2,159.90
8	Red and yellow soil on clay rock (Fs)	G8	240.05	628.30
9	Red yellow humus soil on acidic magmatic rock (Ha)	G9	851.49	1,278.10
<i>Evaluation area</i>			<i>4,948.66</i>	<i>15,429.38</i>
<i>Area not rated</i>			<i>3,091.84</i>	
<i>Total natural area</i>			<i>23,469.88</i>	

3.2.1.2. Topographic criteria - Slope

Topography is one of the factors that form the soil, in other words, the soil groups and types of soil formed in certain terrains are characterized by the distribution of the soil. The results of the assessment of land distribution characteristics by topographic level of the buffer zone of Tam Dao national park in Tam Dao district, Vinh Phuc province are presented in Table 03 specifically as follows: Most of the land in the buffer zone is distributed. At a slope of $\geq 25^\circ$ with 13,100.77 ha concentrated in both subregions 1 and 2; then the soil group at the slope of $0 - < 8^\circ$ with 5,408.57 ha; soil group at slope $\geq 15 - < 25^\circ$ accounts for only 825.39 ha. Thus, it can be seen that the land in the buffer zone of Tam Dao National Park in Tam Dao district is mainly very sloping land.

Table 3. The results of the classification of land slope indicators in the buffer zone of the national park Tam Dao by subregion

No	Indicators	Symbol	Area (ha)	Ratio (%)	Subregion 1 (ha)	Subregion 2 (ha)
1	0 - < 8°	SL1	5,408.57	26.54	903.32	4,505.25
2	≥ 8 - < 15°	SL2	1,043.31	5.12	257.95	785.36
3	≥ 15 - < 25°	SL3	825.39	4.05	286.05	539.34
4	≥ 25°	SL4	13,100.77	64.29	3,501.34	9,599.43
<i>Evaluation area</i>			<i>20,378.04</i>	<i>100.00</i>	<i>4,948.66</i>	<i>15,429.38</i>
<i>Area not rated</i>			<i>3,091.84</i>			
<i>Total natural area</i>			<i>23,469.88</i>			

3.2.1.3. Criteria for the thickness of the soil layer

Corresponding to the soil type/soil group with different soil thickness, the soil layer thickness is divided into 3 levels: > 100 cm; 50 - 100 cm; < 50 cm. According to the actual survey results, the soil layer of the buffer zone of Tam Dao National Park in Tam Dao district, Vinh Phuc province is summarized in Table 04, showing that: Most of the land area of the buffer zone has a thin layer of less than 50 cm with an area of 13,631.77 ha, mainly belonging to the group of red-yellow soil and red-yellow humus in the mountains, this group mainly concentrates in sub-region 2. The land area with thickness > 100 cm occupies the second area with 4,340, 91 ha mainly belongs to alluvial soil group, degraded gray soil on ancient alluvium and sloping soil. Thus, the land in the buffer zone of Tam Dao National Park in Tam Dao district is mainly thin and has a steep slope.

Table 4. Results of classification of soil thickness indicators in the buffer zone of Tam Dao national park by subregion

No	Indicators	Symbol	Area (ha)	Ratio (%)	Subregion 1 (ha)	Subregion 2 (ha)
1	> 100 cm	D1	4,340.91	21.30	1,092.05	3,248.86
2	≥ 50 - 100 cm	D2	2,405.36	11.80	356.73	2,048.63
3	< 50 cm	D3	13,631.77	66.89	3,499.88	10,131.89
<i>Evaluation area</i>			<i>20,378.04</i>	<i>100.00</i>	<i>4,948.66</i>	<i>15,429.38</i>
<i>Area not rated</i>			<i>KDG</i>	<i>3,091.84</i>		
<i>Total natural area</i>			<i>23,469.88</i>			

3.2.1.4. Climatic indicators

The entire buffer zone of Tam Dao National Park in Tam Dao district is divided into two climate zones with different sub-climate characteristics (*Table 05*):

Area KH1: With rainfall $\geq 2,500$ mm (R3), total temperate zone $< 7,000^{\circ}\text{C}$ (T1), number of dry months < 2 months. This is the climate zone that accounts for the majority of the buffer zone area of Tam Dao National Park in Tam Dao district with 19,461.18 ha distributed mainly in subregion 2 with 14,770.57 ha and subregion 1 with 4,690.61 ha.

Area KH2: With the characteristics of rainfall 1,500 - $< 2,500$ mm (R1), total temperature $\geq 7,000 - 8,000^{\circ}\text{C}$ (T2), number of dry months $\geq 2 - 3$ months. This is a climate zone occupying a small area of the buffer zone of Tam Dao National Park in Tam Dao district with only 916.86ha and distributed 258.05 ha in subregion 1, 658.81 ha in subregion 2.

Thus, it shows that most of the land area of the buffer zone is in the Tam Dao mountain range and this is also a feature that needs attention in land use of the buffer zone of Tam Dao national park in Tam Dao district.

Table 5. Result of classification of climate indicators in the buffer zone of Tam Dao national park by subregion

No	Indicators	Symbol	Area (ha)	Ratio (%)	Subregion 1 (ha)	Subregion 2 (ha)
1	Amount of rain ≥ 2.500 mm (R3), Total temperature $< 7,000^{\circ}\text{C}$ (T1), dry month < 2 month	KH1	19,461.18	95.50	4,690.61	14,770.57
2	Amount of rain 1,500 - $< 2,500$ mm (R1), Total temperature $\geq 7,000 - 8,000^{\circ}\text{C}$ (T2), dry month $\geq 2 - 3$ month	KH2	916.86	4.50	258.05	658.81
<i>Evaluation area</i>			<i>20,378.04</i>	<i>100.00</i>	<i>4,948.66</i>	<i>15,429.38</i>
<i>Area not rated</i>		<i>KDG</i>	<i>3,091.84</i>			
<i>Total natural area</i>			<i>23,469.88</i>			

3.2.1.5. Criteria for Irrigation

Water regime is an indicator to establish land quality unit for agricultural land. In the project, the water regime is determined according to the following criteria: the irrigation regime includes active irrigation, semi-active irrigation and non-active irrigation completely dependent on nature; Inundation indicators include mild flooding and no flooding. Information about the water regime is entered into each land block forming a layer of information about the water regime.

The results of the classification of water regime indicators in the buffer zone of Tam Dao National Park in Tam Dao district in Table 06 show that:

Currently, there are 15,684.34 hectares, accounting for 76.97% of the land in the buffer zone of Tam Dao National Park in Tam Dao district, thanks to the inactive water

of rain. Most of the soils belonging to the red-yellow soil and the red-yellow humus in the mountains belong to this group. The area of active irrigated land is only 3,828.66 ha, mainly alluvial soil, gray soil on ancient alluvium, sloping land and soil changed by wet rice cultivation.

Table 6. The results of the classification of water regime indicators in the buffer zone of the national park Tam Dao by subregion

No	Indicators	Symbol	Area (ha)	Ratio (%)	Subregion 1 (ha)	Subregion 2 (ha)
1	No waterlogging, watering due to rain	I1	15,684.34	76.97	3,849.79	11,834.55
2	No waterlogging, semi-active irrigation	I2	865.04	4.24	92.15	772.89
3	No waterlogging, active watering	I3	3,828.66	18.79	1,006.72	2,821.94
<i>Evaluation area</i>			<i>20,378.04</i>	<i>100.00</i>	<i>4,948.66</i>	<i>15,429.38</i>
<i>Area not rated</i>		<i>KDG</i>	<i>3,091.84</i>			
<i>Total natural area</i>			<i>23,469.88</i>			

3.2.1.6. Index of soil fertility

This is a complex indicator consisting of 5 indicators of soil properties, in which total nutrients are synthesized from 4 total indicators (total nitrogen, total phosphorus, total potassium and total organic matter). In addition to total nutrients, the criteria determining soil fertility also include density, soil acidity, mechanical composition and absorption capacity.

The results of soil fertility assessment of agricultural soils in the buffer zone of Tam Dao national park in Tam Dao district (*Table 07*) show that:

The vast majority of land area of the buffer zone of Tam Dao national park in Tam Dao district is low fertility (DP1) with a total area of 9,118.17 hectares, this is a group of soil belonging to gray soil on old alluvium and red-yellow soil on acidic igneous rocks.

Average soil fertility (DP2) occupies an average area with 7,411.34 ha, mainly alluvial soils.

High soil fertility (DP3) is only 3,848.53 ha, this is the majority soil group in the KH1 region and the red-yellow soil group, distributed in both sub-regions of the buffer zone of Tam Dao national park in Tam Dao district.

Thus, it shows that most of the land area of the buffer zone of Tam Dao National Park in Tam Dao district is not very suitable for agricultural crop development.

Table 7. The results of the classification of soil fertility indicators in the buffer zone of the national park Tam Dao by subregion

No	Indicators	Symbol	Area (ha)	Ratio (%)	Subregion 1 (ha)	Subregion 2 (ha)
1	Low fertility	DP1	9,118.17	44.74	2,541.49	6,576.68
2	Average fertility	DP2	7,411.34	36.37	1,277.95	6,133.39
3	High fertility	DP3	3,848.53	18.89	1,129.22	2,719.31
<i>Evaluation area</i>			<i>20,378.04</i>	<i>100.00</i>	<i>4,948.66</i>	<i>15,429.38</i>
<i>Area not rated</i>		<i>KDG</i>	<i>3,091.84</i>			
<i>Total natural area</i>			<i>23,469.88</i>			

3.2.2. Result of building land unit map

The map of land units in the buffer zone of Tam Dao national park in Tam Dao district is made in accordance with the provisions of Circular No. 60/2015/TT - BTNMT which is built on the basis of overlapping 6 single-variant maps: type maps. soil, soil thickness map, slope map, climate sub-region map, irrigation regime map and soil fertility map.

Statistical results of the number of soil quality units have determined that the buffer zone of Tam Dao National Park in Tam Dao district has 51 quality units of agricultural and forestry land. The aggregate data of land units (DVD) by soil quality in the buffer zone of Tam Dao National Park in Table 08 and Figure 01 shows that:

The total area of 51 land units in the buffer zone of Tam Dao National Park in Tam Dao district is 20,378.04 ha, accounting for 82.83% of the total natural area. The total number of circles on the map is 356.

The statistical results of the number of soil quality units distributed in two subregions of the buffer zone of Tam Dao National Park in Tam Dao district showing that:

In subregion 1, there are 22 land units with 4,948.66 ha and the total number of slices on the map is 67. The large land units are DVD 19, 20 and 51.

In subregion 2, there are 49 land units with 15,429.38 ha and the total number of slices on the map is 289. Large land units are also DVD 19, 20 and 51.

Table 8. Statistics of land units (DVD) according to the quality of land in the buffer zone Tam Dao National Park by subregion

No	Land unit	Land characteristics						Subregion 1		Subregion 2	
		Soil type	Slope	Soil layer	Clim-ate	Irriga-tion	Ferti-lity	No of slices	Area (ha)	No of slices	Area (ha)

52	KDG*	KDG	KDG	KDG	KDG	KDG	KDG	3,091.84			
<i>Number of slices/Evaluated area</i>								67	4.948.66	289	15.429,38
<i>Total natural area</i>									23,469.88		23.469,88

Note: * Non-agricultural land

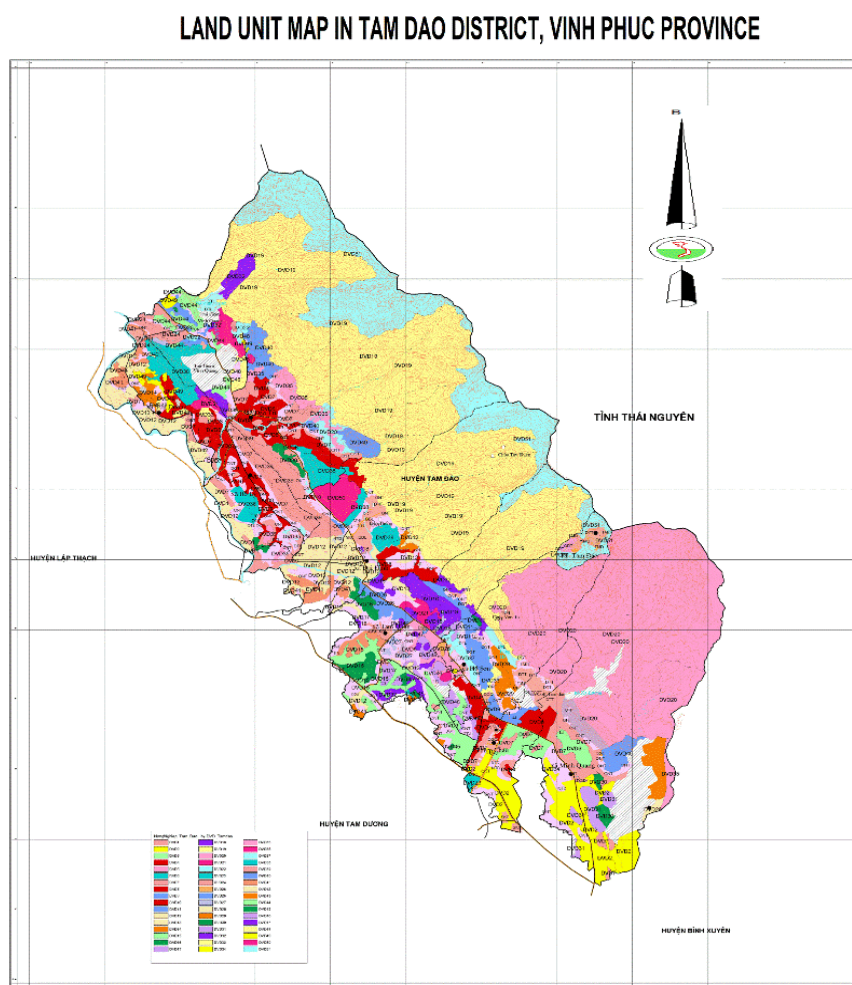

Figure 1. Land unit map (DVD) of Tam Dao district

Based on the combined assessment from 6 groups of indicators of the land unit map, the results of the quality of land in the buffer zone of Tam Dao National Park in Tam Dao district in Table 09 have been obtained, showing that:

In subregion 1: There are 1,191.81 hectares of high-quality land of 16 land units. 4 land units with a total area of 1,118.36 ha are of medium quality and 2,638.49 ha of 2 land units are of low quality.

Table 9. Land unit (DVD) by soil quality in the buffer zone of the national park Tam Dao in subregion 1

No	Rating level	Area (ha)	Land unit
1	High	1,191.81	1-4, 7-10, 12, 14, 23, 35, 41, 43, 45, 46
2	Medium	1,118.36	38, 39, 50, 51
3	Low	2,638.49	19, 20
	<i>Evaluation area</i>	<i>4,948.66</i>	
	<i>Total natural area</i>	<i>23,469.88</i>	

In sub-region 2 (*Table 10*): There are 5,000.41 ha of high-quality land of 38 land units. 9 land units with a total area of 2,810.61 ha are of medium quality and there are up to 7,618.36 ha of land of 2 low quality land units.

Table 10. Land unit (DVD) by soil quality in the buffer zone of the national park Tam Dao in subregion 2

No	Rating level	Area (ha)	Land unit
1	High	5,000.41	1-3, 5-12, 14, 15, 21, 22, 24-37, 41-49
2	Medium	2,810.61	13, 16-18, 38-40, 50, 51
3	Low	7,618.36	19, 20
	<i>Evaluation area</i>	<i>15,429.38</i>	
	<i>Total natural area</i>	<i>23,469.88</i>	

4. Discussion and Conclusion

4.1. Evaluation of soil types in the buffer zone of Tam Dao National Park

The whole district of Tam Dao has 5 soil groups with 9 soil types, the red-yellow soil group has the largest area with 14,222.98 hectares, accounting for 69.80% of the natural area, of which red-yellow soil on acid magma has the largest area with 2,640.03 hectares in subregion 1 and 7,990.42 ha in subregion 2. Land groups with a smaller area are the group of red yellow humus in the mountains, 2,129.59 ha, accounting for 10.45 %, mainly in subregion 2 with 1,278.10 ha. Gray soil group with 1,717.00 ha accounts for 8.43%, Alluvial soil group has only 1,274.32 ha, accounting for 6.25% and Valley soil group is 1,034.15 ha, accounting for 5.08%.

From the results of the area distribution of soil types, it shows that most of the land area of the buffer zone of Tam Dao National Park is sloping and is mainly located on the Tam Dao mountain range.

4.2. Developing a land unit map (DVD) in the buffer zone of Tam Dao National Park

On the basis of overlapping 6 single-use maps: soil type map, soil thickness map, slope map, climate sub-region map, irrigation regime map and soil fertility map, identified the buffer zone of Tam Dao National Park in Tam Dao district with 51 quality units of

agricultural and forestry land. The total area of 51 land units is 20,378.04 ha, accounting for 82.83% of the total natural area. The total number of circles on the map is 356.

In subregion 1, there are 22 land units with 4,948.66 ha and the total number of slices on the map is 67. Land units occupying a large area are DVD 19, 20 and 51. In subregion 2 there are 49 land units with 15,429.38 ha and the total number of slices on the map is 289. Large land units are also DVD 19, 20 and 51.

Out of a total of 20,378.04 hectares of land in the buffer zone of Tam Dao national park in Tam Dao district, there are 6,192.22 hectares of high-quality land, accounting for 30.39%; the average quality land area reached 3,928.97 ha, accounting for 19.28 % and the area of low quality land was very large, up to 10,256.85 ha, accounting for 50.33 %.

The distribution of land area by quality also differs in the two subregions:

In subregion 1: There are 1,191.81 ha of high-quality land of 16 land units, accounting for 24.08 %. 4 land units with a total area of 1,118.36 ha of medium quality account for 22.60% and the area of low-quality land is very large, 2,638.49 ha, accounting for 53.32 %, concentrated in 2 land units 19 and 20.

In subregion 2: There are 5,000.41 ha of high-quality land of 38 land units, accounting for 32.41% of the sub-region. 9 land units with a total area of 2,810.61 ha are of medium quality, accounting for 18.22% and there are 7,618.36 ha of land of 2 low quality land units, accounting for 49.38 %.

From the above results, it is shown that most of the land in the buffer zone of Tam Dao National Park is of medium and low quality. This is a big obstacle for agricultural crop cultivation because a huge amount of fertilizer must be invested, especially organic fertilizer, to ensure sustainable agricultural development in this region.

Nha Trang University, Khanh Hoa, Vietnam*

Abstract

This research analyzes the impact of destination social responsibility on the environmentally responsible behavior of people in Nha Trang City, a famous tourist destination of Khanh Hoa province. Applying stakeholder theory and social exchange theory, this research has built a model with positive and negative impacts of tourism and community satisfaction as mediating variables affecting environmental behavior protection of the community. Research results show that the social responsibility of the destination helps to raise public awareness of the positive impact of tourism, improves community satisfaction, and contributes to promoting behavior to protect the marine environment.

Keywords: *Destination social responsibility, Environmentally responsible behavior, Community.*

1. Introduction

Tourism is one of the fastest-growing economic sectors on a global scale and plays an important role in the economic development strategies of many countries. The development of the tourism industry, therefore, needs to be properly planned and managed, in which the practice of destination social responsibility is considered a key factor for sustainable development. tourism industry (Su et al., 2016). Destination social responsibility refers to the responsibility of destination stakeholders to create economic benefits for local communities, increase welfare and minimize negative economic impacts, on society, and the environment (Su et al., 2016). Previous studies have also shown that environmentally responsible destinations have a positive influence on visitor behavior. Example: Research by Scott McCabe and Stefan Gössling (2015) on tourism, climate change, and sustainability: A review of the literature; How does Su's research (2018) on the Social Responsibility of Destination contribute to environmentally responsible behavior? The point of view of destination residents; Research by Tien-Ming Cheng (2014) on How do environmental knowledge, environmental sensitivity, and attachment to place affect environmentally responsible behavior? An integrated approach to sustainable island tourism.

The sustainable development of the tourism industry and the practice of social responsibility for the destination cannot be without the attention and support of the local community, especially their environmentally responsible behavior. Because the local community at the destination is one of the stakeholders that has the greatest impact on the natural environment at the destination. According to the Stakeholder Theory and Social Exchange Theory, the social responsibility of the destination can create economic benefits for the local people, improve the quality of the destination, their lives, and reduce negative economic, environmental, and social impacts (Su et al., 2016). The benefits obtained for the local community can lead to their satisfaction with tourism development. From there, to gain more benefits from the social responsibility of the destination, the local community can adopt environmentally responsible behavior to protect the natural environment of the destination, contributing to the development of the sustainable destination.

Nha Trang is one of the major tourist centers of Vietnam. The advantage of rich marine resources has promoted the rapid development of the tourism industry in recent times. According to the report “The Situation of tourism activities in Khanh Hoa in 2022” by the Department of Tourism of Khanh Hoa province, tourism revenue is estimated to reach 13,500 billion VND in 2022, 5,6 times higher than in 2021. Staying guests is estimated at 2,540 thousand arrivals, 4,2 times higher than in 2021, with 6,030 thousand days of guests staying, 3.6 times higher than in 2021, of which international visitors are estimated at 250,000 arrivals, 10 times higher than that of 2021, 1 times compared to 2021, with 1,115 thousand days of guests staying, 9 times higher than in 2021; Domestic tourists are estimated at 2,290 thousand arrivals, 3,9 times higher than in 2021. To sustainably develop Nha Trang beach tourism, the tourism industry has implemented many management policies, focusing on the harmony between the environment, the natural environment, and the social environment. The tourism industry is also interested in practicing social responsibility through the development of responsible tourism models that bring many benefits to the local community such as increasing income and improving working conditions for the local community settlement and preservation of natural and cultural heritage. In addition to the benefits achieved, the rapid development of the tourism industry has led to many environmental and social problems. The beaches are often overloaded, the sea is polluted by garbage, and the marine ecosystem is also affected.

This poses a requirement to effectively manage the tourism industry to protect the natural environment and marine tourism resources through the participation of the community, especially responsible behavior for the marine environment from the community.

This research will apply stakeholder theory and social exchange theory to test the direct and indirect effects (through positive and negative effects and community satisfaction) of social responsibility, and destination social responsibility towards environmentally responsible behavior of people in Nha Trang city. From the research results, policy suggestions will also be proposed to manage and develop Nha Trang tourism destinations sustainably and responsibly based on the contribution of the local community.

This research aims to analyze and assess the community's perception of the destination's social responsibility practice, clarifying its impact on the perception of positive and negative impacts of tourism, community, the community's satisfaction with tourism activities as well as their support for tourism development. From there, the research will propose policy suggestions to manage and develop the Nha Trang tourism destination sustainably and responsibly based on community contributions.

To address the above general objective, this research has the following objectives:

Objective 1: To research the impact of the destination's social responsibility on the overall satisfaction of the community.

Objective 2: To research the direct and indirect effects of the destination's social responsibility on the community's support for the development of Nha Trang beach tourism.

Objective 3: Propose some policy suggestions to manage and develop Nha Trang tourism destination sustainably and responsibly.

2. Theoretical basis and research hypothesis

2.1. Theoretical basis

2.1.1. Destination social responsibility

From the traditional point of view, destinations are considered to be areas of harmonious geographical and climatic location, such as a country, an island, or a city (Hall, 2000). From a modern point of view, the destination can also be an emotional concept, subjectively perceived by tourists depending on travel itinerary, cultural background, purpose of visit, education level, and experience. Destination includes areas related to tourism, such as tour operators, transportation, accommodation, restaurants, and travel agencies. These are the key stakeholders that can influence the economic, sociocultural, and environmental aspects of the destination.

A destination includes many areas related to tourism, such as tour operators, accommodations, restaurants, etc. Key stakeholders in this area face challenges related to social responsibility as key stakeholders that can affect the economy, environment, culture, and society of the country's destination. According to Su et al (2016), the social responsibility of a destination is defined as “the collective ideology and efforts of the stakeholders at the destination to carry out socially responsible activities under the awareness of local people”. Or DSR can be understood as the collective ideology and efforts of the parties involved in the implementation of socially responsible activities as perceived by local people (Su et al., 2018). The rationale behind destination social responsibility is that destination sustainability can be achieved if stakeholders work together with a common goal - to act for the common good of society.

2.1.2. Environmentally responsibility behaviour

Environmentally responsible behavior (ERB) is actions that reflect an individual or group's concern for the natural environment and its way of solving problems (Hsu & Roth, 1998). From

that, it can be seen that the community can only be persuaded to perform environmentally responsible behavior if they have built a solid relationship with the environment.

2.1.3. Stakeholders theory

The stakeholder theory proposed by Freeman (1984) holds that an organization is characterized by its relationships with various groups and individuals, including employees, customers, suppliers, government, and members of the community. In a narrow sense, stakeholders are defined as those who participate in the operation of the organization, in other words, they are the people who are very important to the existence and success of an organization (Zammuto, 1984). In a broad sense, a stakeholder is defined as any group or individual who can influence or be affected by the achievement of an organization's goals (Freeman, 1984). Based on the definition by Freeman (1984), Donaldson and Preston (1995) have defined a group or individual that qualifies as a stakeholder if they have a legitimate interest in operational aspects of the organization.

Therefore, in this research, the author identifies four main groups of stakeholders at the destination: people, businesses, organizations, and tourists. Many researchers consider residents as the core stakeholder group (e.g. Byrd et al., 2009; Su et al., 2016), and have demonstrated that residents' perceptions of development and management destination will influence their attitudes and behaviors (Su et al., 2016).

According to this theory, each stakeholder has the right to pursue his or her own goal, not a means to some goal. Therefore, they must participate in determining the future planning of the destination to which they are related. Similarly, this theory holds that “it is the responsibility of the destination to select activities that achieve optimal benefits for all identified stakeholders, without prioritizing any other party's interests over the interests of other stakeholders”.

2.1.4. Social exchange theory

Social exchange theory analyzes interactions between two parties by focusing on the benefits and costs that accrue to each party in the exchange process. This theory argues that interactions and exchanges are likely to continue if both parties feel that they gain more than they lose in the process. From the perspective of tourism development, social exchange theory assumes that the attitudes of stakeholders towards the development and support of tourism development and environmentally responsible behavior in the community will be affected by their assessments of the actual and perceived outcomes of tourism on their communities (Andereck et al., 2005).

In this research, social exchange theory is applied to explain and explore the behavior and attitudes of people at the destination as well as provide a theoretical basis for research and assessment of tourism impacts on people at the destination. In addition, this theory is used to analyze the fact that “local people will tend to participate in the exchange and support of future tourism development in their community if they see the benefits that they get greater than the cost”.

2.2. Research hypothesis

2.2.1. The relationship between the social responsibility of the destination and the impacts of tourism.

Tourism impacts destination stakeholders through positive and negative influences (Byrd et al., 2009) on various aspects such as economic, sociocultural, and environmental (Tosun et al., 2009). According to Tosun (2002), tourism can improve and raise the standard of living of people in a destination but it can also increase the prices of goods and services. While Wang et al. (2006) demonstrate that tourism is a means of cultural revitalization, Pearce (1996) argues that tourism can be a “tool of cultural exploitation” and structural disruption. traditional culture at the destination. Richie (1988) argues that tourism can raise awareness about environmental protection and keep the local community's environment clean. In summary, the social responsibility of a destination can promote positive perceptions of tourism and minimize negative impacts.

From the above basis, the author proposes the first two hypotheses:

H1: The social responsibility of the destination positively affects the public's perception of the positive impacts of tourism.

H2: The social responsibility of the destination negatively affects the public's perception of the negative impacts of tourism.

2.2.2. The relationship between the social responsibility of the destination and the satisfaction of the community.

Community satisfaction is considered an important part of destination planning and development. The social responsibility of a destination can bring many benefits such as increased economic efficiency, protection of the natural environment, and improved quality of life (Su et al., 2016). Therefore, the relationship between the social responsibility of the destination and the overall satisfaction of the community can be positive. The destination's socially responsible activities can increase the value of the destination, which can strengthen the community's satisfaction with the destination. From that, the author put forward the following hypothesis:

H3: The social responsibility of the destination positively affects the satisfaction of the community.

2.2.3. The relationship between the social responsibility of the destination and the environmentally responsible behavior of the community.

“Environmentally responsible behavior” refers to the reflective actions of individuals or groups towards the natural environment and ways of solving environmental problems (Hungerford & Peyton, 1976). Based on the stakeholder theory, local people as the core stakeholders of the destination can benefit from the destination's socially responsible behaviors. Based on the theory of social exchange, when people perceive the benefits of the destination's socially responsible behaviors, they will support the destination’s development

through specific behaviors, such as supporting the development of tourism and implementing environmentally responsible behaviors. From there, both the destination and the people can derive corresponding benefits from the exchange, and accordingly, the exchange will be maintained for a long time. From the above bases, the author proposes the fourth hypothesis:

H4: The social responsibility of the destination positively affects the environmentally responsible behavior of the community.

2.2.4. The relationship between tourism impacts and overall community satisfaction

From social exchange theory, it can be seen that if people perceive the positive benefits of tourism as greater than the negative effects of tourism, they will tend to be satisfied and have a pro-development attitude towards tourism. Therefore, to successfully develop tourism, it is necessary to change people's perception of tourism impacts positively. People's perception of tourism impacts and overall community satisfaction is a topic that has been studied for many years and tested in many research models by many authors, such as Ko et al. (2002), Nunkoo and Ramkissoon (2011). On that basis, the author proposes the next two hypotheses:

H5: The positive impacts of tourism positively affect the overall satisfaction of the community.

H6: The negative impacts of tourism negatively affect the overall satisfaction of the community.

2.2.5. The relationship between the impact of tourism and the environmentally responsible behavior of the community

According to social exchange theory, when people see benefits from the positive impacts of tourism, they will perform positive behaviors including environmentally responsible behavior at the destination. On the contrary, when people only see the damage from the negative impacts of tourism they can stop these behaviors. From the above theory, it can be inferred that the positive impacts of tourism can promote environmentally responsible behavior of residents and vice versa, negative impacts can limit responsible behavior to the environment. their environment. Therefore, the following hypotheses are proposed:

H7: The positive impacts of tourism positively affect the environmentally responsible behavior of the community.

H8: The negative impacts of tourism negatively affect the environmentally responsible behavior of the community.

2.2.6. The relationship between satisfaction and environmentally responsible behavior of the community

From the perspective of local communities, previous research has shown that community satisfaction is an important basis for supporting and supporting their tourism development (Su et al., 2016). Similar results are also confirmed in the research of Vargas Sa'nchez et al. (2011) that there is a positive relationship between community satisfaction and support for tourism development by people. people. On that basis, the author proposes the final hypothesis:

H9: Community satisfaction positively affects their environmentally responsible behavior.

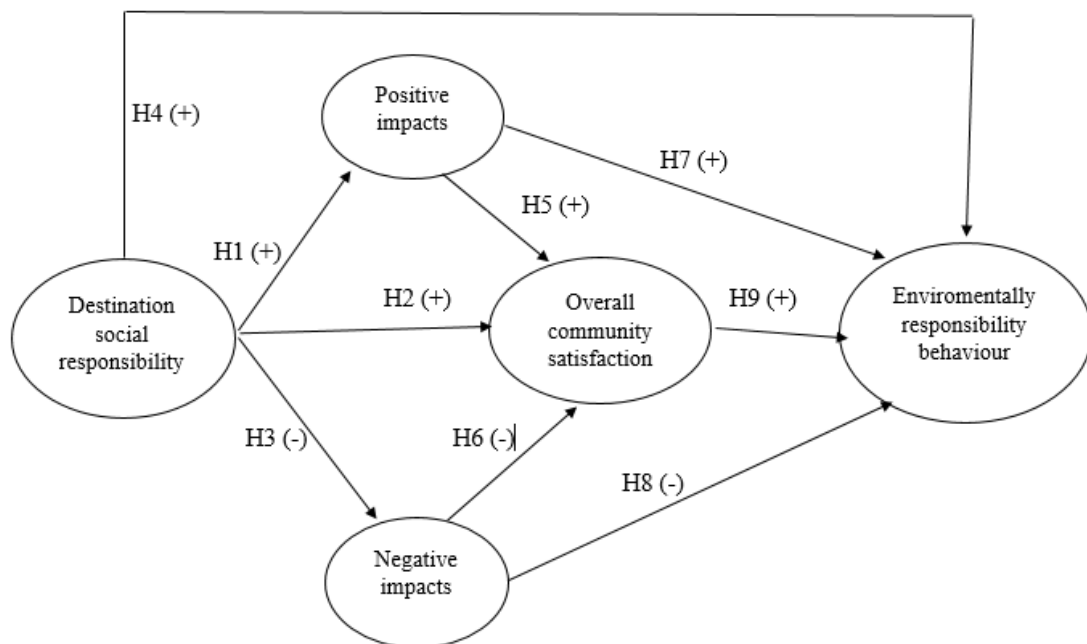

Figure 1. Proposed research model

3. Method

3.1. Research sample

The research focuses on the local community living and working in Nha Trang City. Data collection was carried out from February to April 2021.

This research uses the PLS-SEM data analysis method to evaluate variables and test research hypotheses, so to carry out this research, a large enough sample size is required. According to Hair et al (2014), “the minimum sample size to use exploratory factor analysis (EFA) is 50, preferably 100 or more”. As for the SEM model, Kline (2011) said that: “the sample size is 5 times or better than 10 times the number of observed variables”. Thus, the research model proposed by the author includes 1 independent variable, 3 intermediate variables, and 1 dependent variable, generating 20 observations. And based on the above-mentioned ways of calculating sample size, the minimum sample size of the research is 200, combined with the normative sampling method, the author chooses a sample size of 440 to satisfy the above conditions.

3.2. Methods of data analysis

This research uses the PLS-SEM method through SmartPLS 3.3.2 software to evaluate the reliability of Cronbach’s Alpha, the convergence value, and the discriminant validity of the observations in the research. In addition, PLS-SEM is also used to test the research hypotheses.

For first-order structures, the value of Cronbach’s Alpha and the combined reliability must be greater than 0,7 to ensure the internal consistency of the measurement scales. Next,

evaluate the discriminant validity and the convergent validity. Accordingly, the extracted variance of the structures must be greater than or equal to 0,5 to ensure the convergence value (Anderson & Gerbing, 1988). Besides, according to Fornell & Larcker (1981) criteria, “a structure is considered to be distinguished from other structures when the square root of the extracted variance is larger than the correlation between that structure and other structures”. In addition, to evaluate the discriminant validity, the Heterotrait-Monotrait correlation matrix (HTMT) was also used. This method is considered superior to the criteria of Fornell & Larcker (1981). The maximum HTMT value to ensure the discriminant validity of the studied structures is 0,85.

Finally, the research hypotheses are tested. The quality of the research model is assessed through the R^2 value and the Q^2 index. The reliability of the tests was retested using the bootstrap procedure with 5000 subsamples and 5% significance level. Finally, the research uses the impact magnitude index (f^2) to assess the impact of the relationships in the research hypothesis.

4. Results

4.1. The validity and reliability of the scale

First, the research will analyze the validity and reliability of the scale through Cronbach’s Alpha index, composite reliability (CR), and convergent validity through extracted variance (AVE). Each indicator has a specific requirement. For the reliability of Cronbach’s Alpha, the scale will be selected when the alpha reliability is greater than 0,6 (the larger the alpha, the higher the intrinsically consistent reliability) (Nguyen Dinh Tho et al., 2009). According to Hoang Trong et al. (2005), the combined reliability (CR) must be greater than 0,7 and the value of convergence through extracted variance (AVE) must be greater than 0,5.

The results of the data analysis show that Cronbach’s Alpha values, the combined reliability values, and most of the load factors meet the requirements of each of these indicators.

From the results of the above scales, the extracted variances of the conceptual structures are all greater than the value of 0,50. Therefore, the scales achieve convergent values. The detailed analysis results are shown in the table below:

Table 1. Results of measurement model

Concept structures	Factor loading	Alpha	CR	AVE
<i>Destination social responsibility: Tourism agencies in Nha Trang</i>		0,90	0,93	0,68
Pay great attention to the protection of the marine environment and marine ecosystem.	0,72			
Pay great attention to the lives of local people.	0,79			
Bring about mass of profit for the city's economy.	0,87			

Concept structures	Factor loading	Alpha	CR	AVE
Create many jobs and improve the workers' lives.	0,87			
Build up good relationships with stakeholders and respect them.	0,86			
Always do business ethically and comply with the law.	0,81			
<i>Positive effects:</i>		0,79	0,88	0,71
Marine tourism has contributed to improving the economic situation of Nha Trang city.	0,89			
Marine tourism promotes the construction of many modern works and the development of many available entertainment services.	0,79			
Increases people's awareness of the marine environment.	0,84			
<i>Negative effects:</i>		0,75	0,86	0,67
Increases the prices of goods and services.	0,84			
Increases the number of traffic accidents.	0,86			
Has made the beaches crowded, which has caused the increasing amount of rubbish along the coast.	0,76			
<i>Overall community satisfaction:</i>		0,94	0,96	0,89
Overall, I am satisfied with the conditions in Nha Trang city.	0,94			
I believe in the future conditions of Nha Trang city.	0,94			
Nha Trang will be a worth-living city.	0,94			
<i>Environmentally responsible behavior:</i>		0,97	0,98	0,89
I comply with relevant regulations so as not to destroy Nha Trang beach environment	0,94			
I am willing to participate in activities to protect and clean the beach environment in Nha Trang.	0,92			
I try to convince everyone in the community to join hands to protect the beach environment of Nha Trang	0,94			
I will educate my children to continue to protect and preserve the marine environment	0,95			
I try to avoid behaviors that affect the Nha Trang beach ecosystem throughout my life	0,96			

Note: CR: Composite Reliability; AVE: Average Variance Extracted

Source: Calculated from the author's survey data

To test the discriminant validity of the scales, the research uses the results of the analysis of the Heterotrait-Monotrait correlation matrix (HTMT). In a good model fit, the HTMT index should be below 1,0. Henseler et al. (2015) proposed that if the HTMT value is below 0,90 then a discriminant value has been established between a given pair of constructs. Gold et al. (2001) also use a threshold of 0,90. Besides, Clark and Watson (1995) and Kline (2015) use a more stringent threshold of HTMT criterion at 0,85. The results show that the correlation between the conceptual structures is less than 0,85. Therefore, it can be concluded that the research concepts gain discriminant validity. The results of the HTMT matrix analysis are presented in the table below:

Table 2. Correlation between conceptual structures

Concept structures	1	2	3	4	5
1. Destination social responsibility					
2. Positive impacts	0,70				
3. Negative impacts	0,60	0,77			
4. Overall community satisfaction	0,74	0,81	0,74		
5. Enviromentally responsibility behaviour	0,79	0,72	0,61	0,74	

Source: Calculated from the author's survey data

4.2. Testing the research hypothesis

The results of testing the research hypothesis by PLS-SEM show that eight out of nine proposed hypotheses are supported.

Research analysis results show that the model explains 64% of the variation in environmentally responsible behavior. Based on the impact magnitude index (f^2), the impact of the destination's social responsibility on the perception of the positive impacts of tourism is strong. Meanwhile, the impact of the destination's social responsibility on the perception of negative impacts of tourism, community satisfaction, environmentally responsible behavior as well as the positive impact of tourism to medium-sized community satisfaction. Except, the impact between the perception of negative impacts of tourism on people's environmentally responsible behavior has a magnitude $< 0,02$ so it should be considered no impact, the remaining effects are weak. The Stone-Geisser index (Q^2) of environmentally responsible behavior is 0,56 which is greater than the value 0, thereby proving a suitable research model to explain these variables.

To increase the reliability of the test results, the bootstrap procedure with 5000 subsamples is used to retest the hypothesis. The results show that the bootstrap value range of the statistically significant hypothesis does not contain any values 0. Therefore, the hypothesis estimation results in this research are reliable.

Table 3. Structural model test results and hypothesis test outcome.

	Hypothesis	Std, β	t-value	Bootstrap	VIF	Hypothesis test outcome
DSR → Positive impacts	H1	0,59	13,62***	[0,50; 0,67]	1,00	Yes
DSR → Negative impacts	H2	-0,50	9,71***	[-0,59; -0,39]	1,00	Yes
DSR → Satisfaction	H3	0,37	7,65***	[0,28; 0,46]	1,63	Yes
DSR → ERB	H4	0,43	6,95***	[0,30; 0,55]	2,01	Yes

5. Discussion and Conclusion

5.1. Discussion

This research focuses on discussing and testing the impact of a destination's social responsibility on environmentally responsible behavior, through the perception of tourism impacts and overall community satisfaction. In the context of beach tourism in Nha Trang and Khanh Hoa, the results of the research are completely consistent with and similar to the results of previous research when proving that the social responsibility of the destination is the responsibility of the people at the destination to the perception during tourism development to positively influence their environmentally responsible behaviors. The relationships between the positive impact of tourism, and the general satisfaction of the community with environmentally responsible behaviors are also confirmed in a positive direction, similar to previous research results such as Su et al., 2018; Su et al., 2017; Gursoy et al., 2004. The research also did not find a statistically significant impact between the perceived negative impacts of tourism and environmentally responsible behavior.

According to the research results, there are 3 main factors affecting the environmentally responsible behavior of local people, including Social responsibility for the destination; Community satisfaction; Positive impacts with a degree of influence are arranged in descending order as follows: (1) Social responsibility of the destination with Beta coefficient (0,43); (2) Community satisfaction with Beta coefficient (0,26); (3) Positive impact with Beta coefficient (0,17). This confirms that the social responsibility of the destination plays a very important role in encouraging environmentally responsible behavior in the community.

The social responsibility of the destination has an impact on the public's perception of the positive effects of marine tourism. This result is consistent with the argument of previous research that there exists a statistically significant association between the social responsibility of the destination and the public perception of the positive impacts of tourism. In developing countries, people can support the development of tourism as a means of obtaining benefits and thus place more weight on positive impacts in assessing tourism impacts. Research by Ko et al (2002) has found a relationship between self-interest and the positive effects of tourism. Similarly, Lee's research (2013) used community involvement and attachment and also showed that both community attachment and participation were significantly affected by the benefits they received. Testing of this relationship for local communities in developing countries is rather limited. The results from this research further confirm that the local community in Nha Trang has evaluated and recognized the role of tourism in their lives and communities. In addition, in this research, the author found a statistically significant relationship between the social responsibility of the destination and the community's perception of the negative effects of tourism. This relationship in previous research is usually not statistically significant.

The research also shows that the positive effects of tourism positively affect the satisfaction of the community, while the negative effects of tourism negatively affect the satisfaction of the community. Furthermore, positive impacts have a stronger influence on community satisfaction than negative impacts. This shows that perceived tourism impacts (both positive and negative) are closely related to overall community satisfaction. Since then, promoting the positive impacts of tourism in the process of developing destinations to bring satisfaction to the community is a matter of concern for managers.

Based on the social exchange theory, this research also examines the influence of tourism impacts on people's environmentally responsible behaviors. The positive impact of tourism has a weak effect on people's environmentally responsible behavior. This result is consistent with the view that people's perception of tourism impacts is one of the main predictors of their attitudes and behaviors (Byrd & Gustke, 2004). Similarly, the scale "Community satisfaction" has the second biggest influence on "Environmental responsible behavior". This result is also completely consistent with the previous argument that community satisfaction plays an important role in shaping residents behavior (Ko & Stewart, 2002).

Finally, the research also shows that the social responsibility of the destination has an impact on the people's environmentally responsible behavior and is also the most

influential factor in the environmentally responsible behavior of the people. The experimental results show that socially responsible activities are important activities to improve the satisfaction of the resident community at the destination, thereby promoting their acceptance and implementation, environmentally, responsible behavior. By adopting destination management practices, destinations will be incentivized to effectively implement environmentally responsible behaviors by their people and contribute to the sustainable development of destinations.

5.2. Conclusion

This research has demonstrated that there exists a statistically significant relationship between the social responsibility of the destination and the perception of tourism impacts (positive and negative), community satisfaction, and behavior environmental responsibility of people. Therefore, tourism managers should invest more in the destination's social responsibility initiatives and communicate these initiatives to local people. This will positively influence residents awareness and improve their environmentally responsible behavior.

Stemming from the above arguments, tourism managers in Nha Trang City need to focus on implementing some solutions for sustainable and responsible destination development as follows:

- First, set out standards for assessing the performance of environmental protection as well as environmental assessment standards at destinations. Orienting tourism development in combination with environmental protection, promoting environmentally responsible behaviors for parties involved in tourism development. It is necessary to have regulations clarifying environmentally responsible behaviors for related parties, along with sanctions to handle acts that cause adverse effects on the natural environment and the socio-cultural environment at the destination.

- Second, develop programs and policies to encourage people to participate in tourism: Encourage people to participate in introducing destinations to tourists, providing places to stay, places to eat, and means of transport,...in a controlled manner. Along with that is to develop a clear benefit-sharing mechanism to ensure that people can receive the benefits from tourism development.

- Third, strengthen the work of supporting and encouraging tourism business units to improve their social responsibility; discuss with the people about policies and plans in tourism development to ensure that the development in the destination, brings more positive impacts than negative impacts to the community; providing a satisfactory tourism environment and services, along with monitoring changes in people's satisfaction levels and taking timely measures to resolve them.

- Fourth, focus on training and developing human resources for tourism, especially human resources from the local community.

- Fifthly, effectively exploiting the media in promoting the destination image, the actual benefits that tourism brings, bringing tourism closer to the people, giving directions

and directions, guiding on propaganda programs through the media on the contents to increase understanding, interest, and positive attitude towards marine tourism development.

- Sixth, focus on ensuring security and order, ensuring the quality of people's living environment is not affected by tourism development. There are strict regulations for tourists participating in tourism to avoid adversely affecting people's lives.

Abstract

Environmental, Social, and Governance (ESG) is a new spotlight for investors to seize the opportunity to make intelligent decisions and for corporations to easily follow the trend of the world. But does ESG have long-term value, or is it just a transient phenomenon? Our study aims to test the relationship between ESG standards and the dividend payout policy of corporations, demonstrating the importance of ESG to both corporations and investors. Using data from Refinitiv, we discovered 734 companies, comprising 166 from developing nations and 568 from developed countries, from 2015 to 2021, with an annual frequency of 5,138 observations. Our research findings support our hypothesis: there is a positive relationship between ESG standards and corporate dividend payout policy. This relationship is particularly weakened in light of the COVID-19 pandemic. Along with that is a discovery between the two groups of developed and developing countries, and between the two groups of high-ESG-corporations and low-ESG-corporations about the above correlations. Empirical evidence meets research objectives and is expected to be a reference source for managers to comprehensively evaluate and consider the business decisions of corporations in the current context.

Keywords: *COVID-19, dividend payout, ESG*

1. Introduction

The last decade has seen a "revolution" in the process of dramatic change for the sake of global sustainability. As a result, they started to concentrate on developing projects concerning environmental, social, and governance standards, which is called ESG

(Environment, Social and Governance). Dividend payout policy demonstrates the financial strength and worth of the business, generating goodwill among shareholders and driving stock demand. On the other hand, when investors enter the market, they always yearn to maximize their assets. However, in this day and age, investors not only want to make temporary benefits, but also desire to ensure that future dividends will not be reduced. To protect their own interests, they often invest in businesses with higher sustainability (Garavaglia et al., 2023). Since then, our research has focused on an important factor in sustainability indicators - ESG. Some studies have analyzed the relationship between ESG standard and dividend payout policy, such as the paper of Ellili, N. O. D. (2022). Almost all of them point out a positive relationship between ESG and dividend payout policy, demonstrating that this standard has a significant influence on shareholder interests and the corporation's dividend payout policy. Yet, certain research, such as the empirical study in China - Niccol et al. (2020), reveal a negative association between ESG and dividend payout policy. So, this subject has drawn a lot of attention.

Before the world faced the COVID-19 crisis, activities related to sustainability did not really become popular and explosive. COVID-19 has rattled markets, making investors pay more attention to a corporation's long-term viability when making investment decisions. For corporations, ESG is a strategic and urgent global trend for private and state-owned corporations, directly affecting long-term sustainable development. The good implementation of ESG standards will help corporations improve their brand value and reputation; contribute to reducing costs and increasing productivity; increase revenue; enhance the relationship between customers and partners; create competitive advantages, attract capital and investment, especially foreign investment; etc. (Freeman, 1984). On the other hand, for investors, ESG is a reputable measure for investors to make decisions. However, the authors wonder whether ESG is really important or just a transient phenomenon?

The relationship between ESG and corporations and investors is almost positively correlated. However, ESG scores do not invariably exhibit a favorable correlation with the dividend payout policy of the company. As an instance, social and environmental responsibility, such as ESG, over the short and extended periods will have different impacts on dividend payout policy and shareholders' investment decisions. Therefore, the authors want to clarify the correlation relationship between ESG standard and the dividend payout policy of corporations, thereby showing the importance and strong influence of ESG standards on investors and corporations. Previous studies usually only compare ESG and dividend payout policy within each region, such as Western Europe, the United States, China, and so on, without comparing them across different regions (Verga Matos et al., 2020). The study by Lucas (2020) still has data limitations, as a result, this is our chance to provide empirical evidence comparing two groups of developed and developing countries. At the same time, research papers usually consider a specific stable situation, not mentioning this relationship in the unstable economic situations of the times (particularly the COVID-19 pandemic). In addition, the authors expect detailed analysis of the data to clarify issues surrounding the relationship between ESG scores and dividend payout policy (Broadstock

et al., 2021) divided corporations into two groups based on ESG scores and highly appreciated the performance of corporations with higher ESG scores; however, the data is still limited to one country, China. So, this is our opportunity to provide empirical evidence between two groups of developed and developing countries as well as between corporations with high and low ESG scores, thereby expanding the research problem in different cases.

Objectives of the study including: (1) Provide empirical evidence on the effect of environmental, social, and governance activities on the dividend payout policies of corporations in developed and developing countries; (2) Analysis to show empirically evidence for the difference in the influence of high-ESG-corporation and with low-ESG-corporation on dividend policy; (3) Shows the force of ESG on dividend payout ratio amidst the COVID-19 pandemic.

2. Literature review and theoretical basis

2.1. Literature review

Managers usually use ESG as a quantitative alternative to evaluate the company's impact on society and environment. As maintained by Soppe (2004), sustainability is a phenomenon rapidly spreading across economic and financial literature. Previous studies have only analyzed a small portion of the main impacts of ESG, making it difficult to generalize the results. To address this limitation, Friede et al. (2015) conducted a thorough review that included all primary and secondary data from earlier studies. Scholars and investors have conducted over 2,000 empirical and evaluative studies on this relationship, highlighting that the positive impact of ESG on corporate financial performance (CFP) appears to be consistent over time. ESG is a crucial element that sovereign wealth funds (SWFs) should contemplate when formulating investment judgments, the higher ESG score companies have, the more attractive to SWFs (Dai et al., 2022). We are concerned about whether dividends will face short-term challenges and how investors will respond to them. Black et al. (2002) demonstrated that investors in both the stock market and hedge funds exhibit a short-term orientation. To provide further insight, Harford et al. (2014) have shown that these types of investors typically prioritize short-term returns and overlook long-term. Consequently, investors may tend to undervalue the long-term perspective. In such circumstances, adherence to ESG standards may, in the short term, result in a decline in dividends, which may be upsetting to investors. Lastly, Starks et al. (2017) investigated investors' short and long-term investing tendencies. The findings reveal that investors with long-term objectives typically favor companies with higher ESG scores, while those with short-term goals prefer the opposite. Verga Matos et al. (2020) looked at the correlation between ESG scores and corporate dividend payout policies in Europe, they found that more sustainable firms tend to have more stable dividend payouts. The research indicates that a higher ESG score results in a more enduring connection between shareholders and other stakeholders, owing to a more dependable profit sharing. Lucas (2020) showed the results support a favorable association, indicating that ESG factors continue to have a positive effect on the durability of dividend payments. Recent studies, such as Zahid's research (2022) which analyzed data from Western European listed companies (who were at the forefront of

the ESG revolution) for the period 2010 - 2019, have demonstrated a positive relationship and a significant difference between ESG and dividend payout policies. However, Zahid et al. (2022) also noted that engaging in high-quality ESG activities could lead to a slowdown in dividend growth.

These studies have shed light on the relationship between corporate sustainability and dividend payout policies. As a result, corporations may adopt business strategies related to ESG practices or consider implementing such strategies. Likewise, investors who use ESG screening as a decision-making criterion can benefit from the findings of these studies. However, there are few research studies that objectively consider ESG scores in uncertain circumstances. For instance, it remains unclear whether ESG still has a positive impact on the dividend payout ratio during an economic downturn. To answer this question, the authors use the COVID dummy variable approach to analyze data from 2015 - 2021 for companies operating in both developed and developing economies, while accounting for the COVID-19 pandemic. By comparing developed and developing countries, individual analysis will be conducted on two groups of corporations with low ESG scores and high ESG scores. We hope to provide a comprehensive understanding of the relationship between ESG and dividend payout policy.

2.2. Theoretical basis

Trade-off Theory: According to the trade-off theory found in previous studies on Environmental, Social, and Governance (ESG), typically, the study of Azmi et al. (2021) indicates that investment in ESG is likely to be an inefficient use of resources. From our perspective, in the short term, the investment in ESG negatively impacts shareholders' cash-flow. But over time, corporations will gain from investing in ESG. Besides, on the trend of sustainable development of the world, if we do not change and follow the sustainable rules, sooner or later, we will eventually be "out of the game". Thus, based on the trade-off theory, corporate managers have a choice: a trade-off between shareholders' current cash-flow or the corporation's value and shareholders' interest in the future.

Agency Theory: ESG standards and dividends both have similar goals. Giving the market clear signals increases both the reputation and the governance of the corporations (El Ghoul et al., 2011). Simultaneously, a solid reputation can assist a corporation seek outside funding, which lowers the cost of doing so and allows businesses to set away more money for dividends. Therefore, this view implies a positive relationship between ESG standards and dividend payout ratio. Formulated on agency theory, our study will argue about the information asymmetry problem that makes investors favor dividend payout policy over retained earnings.

Signaling Theory: When corporations disclose information and communicate their actions to the capital markets, it is done with the intention of reducing asymmetric information costs, optimizing financial costs, and increasing the value of the corporations. Signal theory suggests that the more transparent the information is, the more certainty investors have in managers' decisions. This becomes useful in debating and assessing the

impact ESG scores have on managers' investment decisions, and shareholders' positive or negative assessments of the ESG scores of corporations.

Stakeholder Theory: It states that successful corporations can coordinate the interests of all stakeholders to increase their sustainability (Freeman, 1984). They emphasize not only shareholder profit maximization but also the needs of the corporation's other stakeholders. As a new emerging model for corporate strategy, ESG metrics can assess a corporation's achievement and standing on a variety of important issues in the same way that financial ratios can.

The Precautionary Motive: In our study, the precautionary motive theory clarifies why firms are increasing their cash reserves in response to economic volatility and uncertainty resulting from the COVID-19 pandemic. This ensures that the company can maintain its operations and mitigate the impact of this unpredictability.

2.3. Hypothesis

H1: ESG standards positively affect the dividend payout ratio of corporations.

H2: The effect of the ESG standard on the dividend payout ratio of corporations in developing countries is stronger than in developed countries.

H3: In the context of COVID-19, the relationship between ESG and dividend payout ratio is weakened.

H4: The relationship between ESG score and a dividend payout ratio in firms with low ESG scores is stronger than in firms with high ESG scores.

H5: COVID-19 pandemic affects the relationship between ESG and dividend payout policy more strongly in low-ESG-corporations.

3. Method

3.1. Sample

Our dataset has a total of 5,138 observations for 568 companies in developed countries (USA, UK, France, Germany, Spain, Netherlands, Singapore, Japan, Korea, Australia, etc.) and 166 companies from developing countries (China, India, Brazil, Turkey, Indonesia, etc.), in the period from 2015 to 2021, at an annual frequency. We selected the companies in the industry group that have codes 10 (Energy), 15 (Materials), and 20 (Industry) according to GICS standards. We collect data on ESG scores and dividend payout ratios from Refinitiv to build the dataset for the study. Moreover, the data set is truncated at 3% at each tail of the distribution to reduce the influence of outliers.

3.2. Models and methodology

To test the assumed relationship between the Environmental, Social, and Governance standard and the corporation's dividend payout ratio, the authors estimate the following model (Verga Matos et al., 2020; Benlemlih, 2019):

$$DIV_{i,t} = \beta_0 + \beta_1.ESG_{i,t} + \beta_2.DIV_{i,t-1} + \beta_3.WACC_{i,t} + \beta_4.SIZE_{i,t} + \beta_5.CAPEX_{i,t} + \beta_6.LEV_{i,t} + \beta_7.AGE_{i,t} + \beta_8.CASH_{i,t} + \beta_9.CFO_{i,t} + \beta_{10}.ROE_{i,t} + \delta_t + \alpha_i + \mu_{i,t} \quad (1)$$

Where i refers to firm and t refers to periods; δ_t is the error term in correlation to time-specific effects; α_i is the error term associated with firm-specific effects which include unobservable firm-specific characteristics, and $\mu_{i,t}$ is the random error term.

Second, to show the effect of the COVID-19 pandemic on the relationship between the ESG standard and the corporation's dividend payout ratio, we add a dummy variable COVID (COVID) to model (1) and make an interaction term with the ESG score (ESG), with an essential explanatory variable being ESG x COVID as in model (2) as follows:

$$DIV_{i,t} = \beta_0 + \beta_1.ESG_{i,t} + \beta_2.DIV_{i,t-1} + \beta_3.WACC_{i,t} + \beta_4.SIZE_{i,t} + \beta_5.CAPEX_{i,t} + \beta_6.LEV_{i,t} + \beta_7.AGE_{i,t} + \beta_8.CASH_{i,t} + \beta_9.CFO_{i,t} + \beta_{10}.ROE_{i,t} + \beta_{11}.ESG_{i,t}.COVID_t + \beta_{12}.COVID_t + \delta_t + \alpha_i + \mu_{i,t} \quad (2)$$

Third, to show the impact of the difference between the two groups of low and high ESG corporations on the relationship between ESG and dividends, we estimate the model:

$$DIV_{i,t} = \beta_0 + \beta_1.ESG_{i,t} + \beta_2.DIV_{i,t-1} + \beta_3.WACC_t + \beta_4.SIZE_{i,t} + \beta_5.CAPEX_{i,t} + \beta_6.LEV_{i,t} + \beta_7.AGE_{i,t} + \beta_8.CASH_{i,t} + \beta_9.CFO_{i,t} + \beta_{10}.ROE_{i,t} + \beta_{11}.LOW_{i,t} + \beta_{12}.LOW_{i,t}.ESG_{i,t} + \delta_t + \alpha_i + \mu_{i,t} \quad (3)$$

Fourth, to show how the impact of COVID-19 on each group of firms with high and low ESG scores affects the relationship between ESG scores and dividends, the authors estimate the model:

$$DIV_{i,t} = \beta_0 + \beta_1.ESG_{i,t} + \beta_2.DIV_{i,t-1} + \beta_3.WACC_t + \beta_4.SIZE_{i,t} + \beta_5.CAPEX_{i,t} + \beta_6.LEV_{i,t} + \beta_7.AGE_{i,t} + \beta_8.CASH_{i,t} + \beta_9.CFO_{i,t} + \beta_{10}.ROE_{i,t} + \beta_{11}.COVID_{i,t} + \beta_{12}.ESG.COVID_{i,t} + \beta_{13}.LOW_{i,t} + \beta_{14}.LOW_{i,t}.ESG_{i,t}.COVID_t + \delta_t + \alpha_i + \mu_{i,t} \quad (4)$$

Table 1. Variable definitions

Variables	Definitions	Sources
<i>Dependent variable</i>		
DIV	Divide the cash dividend by the total assets at time t to calculate the dividend payout ratio	Calculations based on data from Refinitiv
<i>Key independent variables</i>		
ESG	The ESG total score can be measured using the natural logarithm at time t	Calculations based on data from Refinitiv
DIV _{t-1}	Divide the cash dividend by the total assets at time t-1 to calculate the dividend payout ratio	Calculations based on data from Refinitiv
<i>Control variables</i>		
WACC	Calculated using all sources of capital including equity stock, preferred stock and debt at time t, with each category of capital being weighted proportionally	Calculations based on data from Refinitiv
SIZE	Measured by the natural logarithm of the total assets of the firm at time t	Calculations based on data from Refinitiv

Variables	Definitions	Sources
CAPEX	The efficiency of using capital on assets of the corporation at time t	Calculations based on data from Refinitiv
LEV	Measure the capacity and manage by total debt on total assets owned by the corporation at time t	Calculations based on data from Refinitiv
AGE	Measured by the natural logarithm of the age of the corporation	Calculations based on data from Refinitiv
CASH	The cash ratio measures the ratio of cash holdings to total assets at time t	Calculations based on data from Refinitiv
CFO	Calculated by corporation's cash flow from operating activities to total assets at time t	Calculations based on data from Refinitiv
ROE	Express the earnings power and efficient capital of corporation by measuring net income on equity at time t	Calculations based on data from Refinitiv

Regarding econometric methods, we use a fixed-effects model (FEM), a random-effects model (REM) and the System GMM method (SGMM). The authors further test whether there is a difference between high-ESG-corporation and low-ESG-corporation on relation to dividend by using the LOW dummy variable on the magnitude of the ESG score and letting it interact with the primary independent variable of the model. Finally, the author allows these two dummy variables to interact with the primary independent variable of the model, thereby examining the force of COVID-19 on the affiliation between ESG and dividends of two different groups of high-ESG-corporation and low-ESG-corporation.

Source: Authors' calculation.

Regression results with the independent variable ESG have a positive correlation with dividend policy at the 5% statistical significance level and have a regression coefficient of 0.0264. This supports our hypothesis: when corporations implement and focus on environmental, social, and governance (ESG) standards, it will positively affect their dividend payout policy. The implication is that when companies improve their ESG scores, their dividend payout ratio will increase, which is in keeping with previous research (Verga Matos et al., 2020; Zahid et al., 2022; etc.).

Source: Authors' calculation

The regression table results exemplify that the influence of ESG on dividend changes across regions. The regression coefficient of the ESG variable in developing countries is 0.0317, which is greater than the coefficient of the ESG variable in developed countries (0.0250). The implication is that: The influence of the ESG standard on the dividend policy of corporations in developing countries is highly stronger than that of corporations in developed countries, which is consistent with our hypothesis and expectancy.

4.3.1. ESG and dividend payout ratio: The impact of COVID-19

ESG.COVID's regression coefficient is 0.0143, which is lower than the independent variable ESG's regression coefficient of 0.0175. In other words, although there is still a positive correlation, the force of the ESG factor on dividend payout policy in the time of COVID-19 is not as great as it usually is. This is in accordance with the findings of prior studies (Mazur et al., 2020; Ali et al., 2022; etc.) as well as consistent with our hypothesis and expectation: In the setting of COVID-19, the relationship between ESG and dividend payout ratio is weakened.

4.3.2. ESG and dividend payout ratio: the difference between high-ESG-corporation and low-ESG-corporation

In accordance with statistical evidence, the impact of ESG on dividend policy varies with different ESG ratings. The regression coefficient of the variable LOW.ESG in the group of corporations with low ESG scores is 0.1210, higher than the regression coefficient of the ESG variable representing the average ESG score of the population (0.0321). The implication is that the influence of the ESG standard on the dividend policy of corporations with low ESG scores is stronger than that of corporations with high ESG scores, and this is consistent with our hypothesis and expectations.

4.3.3. ESG and dividend payout ratio: the difference between high-ESG-corporation and low-ESG-corporation in the scene of COVID-19

To consolidate the conclusion in section 4.3.3.1, the authors divided corporations and found that the relationship between ESG and dividends is negatively affected, especially for firms with low ESG scores in social instability. LOW.ESG.COVID has a regression coefficient of 0.0075, which is lower than the variable ESG.COVID's regression coefficient of 0.0290. That is, although there is still a positive correlation, the impact of the ESG standard on the dividend payment policy of companies with low ESG scores is much smaller than that of companies with high ESG scores during the COVID-19 period. This is consistent with our hypothesis and expectations: COVID-19 pandemic affects the relationship between ESG and dividend payout policy more strongly in low-ESG-corporations.

4. Discussion and Conclusion

The research results have confirmed our expectations, hypotheses, and original objectives. It has been shown that Environmental, Social, and Governance (ESG) standards have a positive influence on the dividend payout policies of corporations. Corporations that strive for sustainability will have a competitive advantage over their competitors (Ioannou et al., 2019). Combined with the stakeholder theory, corporations that are closer to the goal of sustainable development need to consider and meet the interests of all stakeholders. According to the trade-off theory, in order for corporations to fully and truly apply ESG standards to their operations, they must accept the trade-off of necessary resources. Therefore, managers may tighten the dividend payout policy in the short term as a consequence of investing in sustainable development. But in the long term, when corporations have made achievements in implementing sustainability, they will signal to

investors and stakeholders to attract attention and investment opportunities. When investors, particularly risk-averse investors, see a company with a high ESG score, their faith in the company is increased because a high ESG score indicates that they can invest safely in this business when corporate assets are secure and working capital is stable (Wang & Chen, 2017). Similarly, investors usually possess stocks of corporations that exhibit greater information transparency, improved corporate governance, and diminished. Corporations that have strong ESG performance usually reveal more transparent and clear information. Such corporations are prepared to uphold their social engagements and exhibit long-term growth capability, which not only helps avoid environmental hazards and other significant risks linked with the initial investment but also minimizes underperformance in investments.

Notably, ESG standards have a stronger influence on developing-country corporations' dividend payout policies than it has on developed-country corporations. In order to move forward and become developed countries, developing countries not only need to overcome economic limitations but also have to focus on combining economic and other aspects of sustainable development such as ESG. The adoption of ESG norms in this group of countries will be a significant step forward, awarding them with "prizes" from the market and society. Nevertheless, adoption of ESG standards is still relatively new for governments, policymakers, Corporations, and investors in the developing countries. As a result, even if ESG is used, the level of influence on the group of developed countries will be smaller and weaker than for the group of developing countries. Following the catch-up effect states that developing nations frequently experience faster growth than developed nations. Developing countries have the ability to access and use their abundant human resources to apply new innovations from developed countries, thereby building their image and confidence with investors to attract capital and increase growth. Therefore, when applying the ESG standard, developing countries often experience rapid growth, thereby demonstrating that the positive force of ESG scores on developing countries is stronger. With a higher level of interaction than in corporations implementing ESG in developed countries, investors are more easily drawn to the investment environment in developing countries, leading to more investment in ESG-compliant corporations there.

Corporations have limited resources, such as costs, personnel,... and the difference in regulations and political institutions is also a big challenge. This leads to a classification of ESG score: high-ESG-corporations and low-ESG-corporations. However, because of the rapid changes in the world and the need for businesses to perform well in terms of environmental, social, and governance factors, investors prefer to put their money in places that will yield a higher return, such as corporations with high ESG scores (Barker & Eccles, 2019). However, corporations with higher ESG scores have lower risk, and the required rate of return will also be lower. And the fact that corporations have high ESG over an extended period will make the impact of ESG on corporate factors, namely dividend payout ratio, more stable and less volatile. This leads to a slow dividend growth (Zahid et al., 2022). According to Catch-up Effect, corporations with low ESG scores tend to grow faster than corporations with high ESG scores. Specifically, low-ESG-corporations scores will have room to develop and improve growth rates. Because there is investment capital, corporations

have the conditions to overcome the challenges and barriers mentioned above to continue to innovate and improve ESG scores. The dividend growth rate of low-ESG-corporations ratings will be faster and more pronounced than that of high-ESG-corporations scores when investing in ESG is simultaneously increased in both groups of corporations.

The study also shows that, during the severe COVID-19 pandemic, the impact of ESG on dividend policy has decreased compared to the normal situation. The authors find that ESG has a strong growth in this period (2020) because the heavy losses in many areas have prompted policymakers, non-governmental organizations, and even corporate executives to prioritize performing investments more sustainable. When combined with the regression results, it demonstrates that the business's dividend payout ratio, while lower than in the non-COVID situation, actually still increases in volatile times. To support our point of view, Hwang et al. (2021) found that when the COVID-19 pandemic struck, corporate profits decreased significantly; however, as the performance of ESG activities increases, the reduction in income becomes relatively minor. Hypothesizing and proving by econometric method, we also conclude that COVID-19 weakens the relationship between ESG and dividend payout ratio of firms with lower ESG scores than in those with higher ESG scores. Investors frequently place more (less) confidence in companies with higher (lower) ESG scores during times of market-wide crisis. Corporations with high ESG scores are more inclined to survive the pandemic, because investors are more patient and do not sell stocks to avoid losses during volatile market times. This empirical evidence supports the view of the authors that investors will feel more secure about the dividends they receive if the dividend payment policy decided by the managers at the corporation has a high ESG score. Besides, corporations with high ESG scores will attract more investment capital, so they often have abundant financial resources. Therefore, when COVID-19 appears, they will have more financial resources to support business operations than corporations with low ESG scores. Therefore, activities related to social responsibility such as CSR, ESG, etc. are capable of helping corporations cope with and recover relatively from risks in moments of crisis. This is quite true for corporations with a high ESG score, although they are not "completely immune" because they are still relatively affected by COVID-19. Consequently, it can be said that corporations with high ESG scores will be better "protected" than corporations with low ESG scores in the case of the COVID-19 pandemic.

In terms of data, our study complements the previous research direction by expanding to an international context, using data from both groups of developed countries and developing countries from 2015 - 2021 with frequency by year. Using the dependent variable DIV and the independent variable ESG in the analytical model to prove that the group's hypotheses are consistent with the actual situation. In addition, to add certainty to the results, the authors use tests to ensure the confidence level. However, the control variables are not as statistically significant as we expected. The reason is that the search for data is still limited due to the company's limitations in the energy, industrial, and raw materials industries. However, taking data belonging to these industry groups will bring a clearer and more detailed analysis effect because the level of influence of corporations on environmental, social, and governance (ESG) issues seems to be stronger.

The study's findings affirm the significance of ESG standards and their favorable impact on diverse areas, including corporate dividend payout policies, which is consistent with prior research. At present, in developing countries, most of the implementation of ESG is only encouraging, not mandatory, for corporations. Despite this, with climate change and severe environmental pollution affecting the world at large, we believe that the implementation of ESG is no longer an option but has become an obligation of every corporation. Corporations should not only follow the trend but should implement ESG in the most practical way to both bring value to themselves as well as benefit society. While developing ESG, they should also prioritize other factors such as audit quality and management setup to gauge the impact of ESG on dividend payout policies. Through this approach, corporations can determine the. With this in mind, investors can make investment decisions more carefully and thoughtfully. However, the authors still assess that ESG is not yet a factor to measure the performance of corporations. The arguments and recommendations above highlight the significance of ESG standards concerning a corporation's dividend payout policy. Nonetheless, the authors maintain that ESG is not the sole factor that measures a corporation's performance. ESG has the potential to minimize asymmetry of information, enabling investors to make transparent and well-informed investment decisions. However, relying solely on ESG scores to evaluate a corporation's performance may not always be wise, as dividends are impacted by various other factors. Making decisions based on an ESG score without assessing the actual context can lead to biased and inaccurate conclusions. Therefore, investors should adopt a comprehensive approach and scrutinize the corporation's investment model and business operations to make astute decisions that will maximize their benefits.

The above arguments demonstrate that the combination of ESG and dividend payout policy is advantageous for investors. Nonetheless, caution should be exercised when applying the conclusions of this study to firms beyond the industry group that we researched. Therefore, the authors hope that future studies will broaden the scope to enhance the generalizability of experimental results and increase the accuracy of global practices.

ENVIRONMENTAL BARRIERS FOR VIETNAM'S SEAFOOD EXPORTS TO EU MARKET: STATUS AND IMPLICATIONS

Assoc. Prof. Dr. Dinh Duc Truong

truongdd@neu.edu.vn

*Faculty of Environmental, Climate Change and Urban Studies,
National Economics University, Hanoi, Vietnam*

Abstract

Seafood is one of Vietnam's leading export products, and the European Union (EU) is one of the five most important markets. The successful signing of the EU-Vietnam Free Trade Agreement (EVFTA) has opened up many opportunities for Vietnamese seafood in this market, along with difficulties, notably illegal, unreported and unregulated fishing (IUU) yellow card, and food safety and hygiene regulations. Hence, this research aims to clarify the situation of Vietnamese seafood in the EU market and offer solutions to mentioned difficulties. This is a qualitative secondary research, based on data, information and figures provided by official sites and previous researches in order to reach further conclusions. In the Discussion section, predictions about the market trends were involved, emphasizing the outstanding challenges and opportunities in the seafood industry, which leads to recommendations for four main targets: removing IUU yellow card, ensuring food safety standards, encouraging green business strategy and products promotion.

Keyword: *European Union (EU), seafood export, Vietnam, Illegal unreported and unregulated fishing activities (IUU), Sanitary and Phytosanitary Measures (SPS), regulations.*

1. Introduction

In recent years, trade liberalization has been developing strongly in the world. The main content of the trade liberalization process is to gradually eliminate tariff barriers and non-tariff barriers, creating favorable conditions for the exchange of goods and services to develop. Following the flow of this trend, many economic organizations, regional alliances, and free trade agreements have been established. Over the past two decades, the tariffs applied have been gradually reduced, from 10% in 2000 to 7% in 2015 (Kinzius, Sandkamp, & Yalcin, 2019). From 1995 to 2014, global agricultural trade volume increased steadily and quickly, averaging over 3.5 percent per year (Beckman, Dyck, & Heerman, 2017).

The quick advancement in worldwide trade contributes to economic development and welfare advantage in all members, particularly the developing countries. However, the disparity of distribution of the profit from global trade in different countries could lead to tensions in international trade, could prompt protectionism policies to maximize trade benefit at the cost of loss in trade partners. International trade barriers have the forms of tariff and non-tariff barriers. Non-tariff barriers are more flexible and could be applied to target specific countries, industries, or products, which has been used more frequently in

international trade after the international financial crisis (Yao, Yizhen, & Jianping, 2021). Although, in theory, the WTO only recognizes tariffs as the only legal protection tool, the reality has proven that governments are constantly using new non-tariff measures (Khanh & Binh, 2020). As NTBs can be very diverse, we distinguish four groups of NTBs: (1) import controls, (2) state aid and subsidy measures, (3) public procurement and localization policies, and (4) other NTBs, which include Sanitary and Phytosanitary Standards (SPS), Technical Barriers to Trade (TBT) and capital controls (Kinzius, Sandkamp, & Yalcin, 2019).

Industrialized countries more commonly use Non-tariff measures on exports from developing countries than on exports from industrialized countries, mainly industrial products (textile products, footwear, seafood) subject to non-tariff standards. Therefore, these barriers, developing countries must find ways to overcome these barrier to trade with developed countries. Vietnam began to open up its economy and integrate more thoroughly into the international economy when the Party launched the Doi Moi program in 1986. Up to now, Vietnam has completed signing 15 FTAs at the bilateral and regional levels and is negotiating two more. The most prominent are three new-generation FTAs, including the Comprehensive and Progressive Agreement for Trans-Pacific Partnership (CPTPP), the Free Trade Agreement between Vietnam and the European Union (EVFTA), and the Free Trade Agreement between Vietnam and the European Union.

Vietnam is also a trading partner with over 100 countries and a member of numerous regional and international commercial and economic organizations. Thanks to open-door policies and connecting the economy with the world, Vietnam set new milestones in commodity exports. For the EU market, after three months of implementing the EVFTA agreement, exports to this market reached about 11.08 USD, an increase of about 5% compared to the same period in 2019. However, the export of Vietnam's seafood into this market is slowing down due to technical barriers from the EU. With the scale aquaculture and fishing characteristics, Vietnam's fisheries face a significant challenge related to the IUU yellow card warning of the European Commission (EC) from October 2017. IUU yellow to trade with developed countries card has caused Vietnam's seafood exports to this market to decrease continuously. In the past time, Vietnam has also been making many efforts to remove the yellow card warning from the European Commission, including reviewing and completing the legal framework to manage fishing activities strictly, handling enforces violations or allowing violations to occur, investing in and upgrading fisheries infrastructure, guide and inspect each locality in promoting propaganda about IUU.

This article analyzes the current situation of Vietnam's seafood exports to EU countries, challenges and recommendations to remove barriers imposed by these countries. Aside from the literature review on the relationship between trade and the environment and non-tariff barriers, the content of the article will focus on 4 main groups, including (i) Current status of Vietnam's seafood exports to the world and the EU, (ii) Regulations on food safety and environment of EU in seafood import hygiene and food safety, (iii) Challenges for Vietnam's seafood export industry facing with EU regulations and (iv) Solutions recommended for Vietnam.

2. Method

This study includes an overview of Vietnam's seafood exports to the world markets in general and the EU market in particular, through which there can be a correlation, comparison, and difference between markets. Other markets and the EU market. The study focuses on the EU market, so other aspects of this market are also analyzed, the most important of which are (1) the anti-IUU regulation adopted by the European Commission promulgation and (2) EU Food Safety Law. Regarding events, the two main events analyzed in the study are about (1) Vietnam - European Union Free Trade Agreement (EVFTA) taking effect and (2) Vietnam's yellow card in the European market. The conceptual model of the research is presented in the following figure 1.

This is a long-established research topic, but there is always a cross-cutting issue that the government, businesses, and researchers are widely concerned about. Our team has taken advantage of that to collect specific information and data provided by official sites such as Ocean and Fisheries - European Commission or EU IUU Fishing Coalition. For information on the Vietnamese side, the data is taken from reliable sources belonging to state agencies to ensure objectivity and have the most accurate view of Vietnam's point of view on the issue. Seafood exports and the government's efforts promote trade and overcome significant problems. The aggregated figures were all updated to 2020, so they were not outdated when included in the study. After synthesizing the data, we analyze and come up with solutions to the problem and predict the changing trend of the market.

3. Result

3.1. Current status of Vietnam's seafood exports to the EU

For many years, the European Union (EU) has always been known as one of Vietnam's leading seafood export markets. In 2016, the total export turnover of Vietnamese seafood to the EU reached 1.16 million USD and until 2019, it reached 1.29 million USD (VASEP, 2020). The growth of Vietnam's seafood export turnover to the EU from 2016 to 2019 is shown in the following graph 2.

However, Vietnam's seafood exports to the EU have faced many difficulties, including food safety standards and import tariffs (Duijn, Beukers, & Pijl, 2012). Especially from October 2017 - the time when Vietnam was imposed a yellow card by the European Commission (EC) IUU (Customs declaration) illegal, undeclared and unregulated property) (Phuong & Huy Hoang, 2019). Therefore, seafood exports to the EU have decreased continuously from 2018 to 2020, although the previous years have consistently recorded a reasonable growth rate.

On August 1, 2020, the Vietnam - European Union Free Trade Agreement (EVFTA) officially took effect, which is expected to create a breakthrough opportunity for Vietnam's seafood exports to the market (Tuan & Trang, 2020). Thanks to a series of commitments on preferential tariffs, the EU has made Vietnamese seafood more competitive in price than similar products in neighboring countries. FDI attraction is expected to increase, production technology and product quality are focused on improving to meet EU standards; The business and institutional environment is ensured in a more stable and transparent direction because the legal system has also been adjusted and supplemented with regulations to be consistent with the signed FTA.

Figure 2. Total seafood exports of Vietnam to the EU (Million USD)

Source: MOIT, 2020

Nearly one year since the EVFTA took effect, Vietnam's seafood exports to the EU have been changing as Vietnamese enterprises actively promote the export of seafood products that are eligible for incentives from EVFTA in the past year. While the partner also prioritizes choosing seafood products from Vietnam because of the more competitive price. In the first six months of 2021 alone, Vietnam's seafood was exported to 25/27 EU markets with a total export volume of 104.3 thousand tons, worth \$485.3 million, up 16% in volume (MOIT, 2021), which is 20% higher than the same period last year. Export turnover to the EU market accounted for 11.8% of the total seafood export turnover of the country. The largest export markets in this market block are the Netherlands, Germany, Italy, Belgium, and France. This is a relatively positive result, especially in the context that the global economy was severely affected by the Covid-19 pandemic, freight rates increased to record highs while exporting Vietnamese seafood. The IUU yellow card has not yet been removed from the EU market.

Shrimp exports to the EU have grown enormously. Shrimp is an item with preferential import tax under the EVFTA that is cut immediately, according to the 3, 5-year roadmap; shrimp is processed according to the 7-year roadmap. Shrimp exports to the EU market in 6 months reached 255.7 million USD, up 27.5% over the same period in 2020. In which, vannamei shrimp alone reached over 205 million USD, up 31%. The EU market accounts for over 14% of Vietnam's total shrimp export turnover, ranking third after the US and Japan. Another seafood export from Vietnam to the EU is tuna. Tuna exports to the EU increased by more than 31%. Preferential import tax under EVFTA on fresh, frozen, or chilled tuna fillets will be reduced immediately (except frozen tuna loins/fillets); for canned, processed tuna (such as canned, bagged, canned tuna, fish products of the canned tuna family...), the EU exempts Vietnam from tax within a quota of 11,500 tons/year. In the first six months of 2021, tuna had the second-largest export value to the EU, reaching 73.3 million USD, up 31.6%. The EU market accounts for 21% of Vietnam's total tuna export turnover, ranking second after the United States. The export of canned tuna alone reached 35.5 million USD, up 116.6% over the same period last year (MOIT, 2021).

3.2. Regulations on food safety and environment of EU in seafood import hygiene and food safety

Food Safety Law in the EU

The European Commission (E.C.) is responsible for much of the current Food Safety laws in European Union (E.U.) nations rather than national authorities. The Commission can implement new food regulations using two primary regulatory instruments: (1). The first is Directives, which set a goal but enable national authorities to define it as attainable, and which cannot be implemented in the member state until it is codified into national law. (2). The second instrument is Regulations, which are "directly applicable" and become law in all Member States as soon as they enter into effect, without the need for national legislation to be changed. The Directives and the Regulations can be classified as "equal," addressing one characteristic of food across all commodities, such as sanitation, or "upright," addressing individual foods (VASEP, 2013)

The General Food Law is based on the framework of European food regulation. It stipulates that all food sold in the European Union must be hygienic. It establishes rules for food chain transparency. Other E.U. food regulation is built on these principles, which constitute a horizontal framework. The new legislation on importing new food goods in general, fisheries or agricultural commodities in particular, is mirrored in four E.U. legal systems, with the dominating law, law 178/2002/E.C., and four supplementary laws, including 852/2004/E.C., 853/2004/E.C., 882/2004/E.C., and 854/2004/E.C (VASEP, 2013).

a. Regulation 178/2002/ EC: General Food Law

The European Parliament and the Council pass legislation that establishes the food law system's broad principles and requirements, establish the European Food Safety Authority, and prescribes food safety procedures. The Food Law controls processing within European food regulation, requiring that all food sold in the E.U. be safe. It establishes rules for food chain transparency. Other E.U. food regulation is built on these principles, which constitute a horizontal framework. Complete information on the competent authorities responsible for the organization and administration of food safety and hygiene - guaranteeing equivalence with the E.U. legislative framework by collaborating directly and universally between the exporting country's relevant authorities (E.C, 2002).

b. Regulation 882/2004/EC: Official Control Procedures

Control procedures to guarantee that food and feed regulation is followed. Developing countries that export food to the E.U. must disclose details on how their national food inspection systems are organized and administered and ensure legal conformity. Food additive requirements (Directives 89/107/EEC and 95/2/EC); Labeling requirements (Directive 2000/13/E.C.); Animal health standards for goods of animal origin imported from foreign countries (Directive 2002/99/E.C.); Maximum permitted residue levels (Regulation 396/2005/E.C.; Regulation 2377/90/E.C.; Regulation 2073/2005, as revised by Regulation 1022/2008/E.C.; Directive 96/22/EEC and Directive 97/98/EEC); Chemical residue control programs for aquaculture (Directive 96/22/E.C. and Directive 96/23/E.C.) (E.C, 2004).

c. Regulation 852/2004/EC: Regulation of general hygiene requirements for all food business establishments

Update food hygiene standards to provide a consistent and comprehensive policy covering all farm food to the customer's point of sale. It excludes topics such as nutrition, food components, and food quality. Community or similar hygienic standards will prepare food imported into the Community. Animal-derived foods exported outside the Community must at the very least meet the rules that would apply if they were sold in the Community, as well as any additional restrictions that may be imposed. The importing country has placed an order. Basic food hygiene requirements include basic production requirements, technical requirements, HACCP standards for food handling and processing, registration/licensing for establishments that manufacture food, and national guidelines for good practice. Regulation (E.C.) 852/2004 specifies requirements based on the HACCP standard but does not mandate its application to primary production.

d. Regulation 853/2005/EC: Specifies additional requirements specific to establishments that process food of animal origin, including raw bivalve mollusks and aquatic products

Animal-derived foods specified in this regulation may pose microbiological and chemical risks. These rules go hand in hand with Regulation 852/2004 on food hygiene, essentially concerned with operator approval. This regulation applies to unprocessed and processed animal-derived goods, except foods containing a component of plant-derived products (E.C, 2005).

e. Regulation 2073/2005/EC: Microbiological Standards Regulations

One of the essential regulations implemented for all food businesses is Regulation 2073/2005/E.C. (Regulation 2073/2005/E.C. on microbiological criteria for foodstuffs) on microbiological criteria for foodstuffs, commonly referred to as the MCR, effective January 1, 2006. This regulation brings together food-specific microbiological criteria previously scattered across several vertical indicators and presents them in one popular format. Microbiological Standard (2073/2005/E.C.) (applied from 01/01/2006 and expired on 31/12/2009).

f. Regulation 466/2001/EC: Regulations on Food Contaminants

On March 1, 2007, three new European Regulations came into force to deal with a wide range of chemical contaminants in food. The most important of the Regulations from a food industry site is Regulation 1881/2006/E.C., which replaces Regulation 466/2001/E.C. and sets maximum allowable levels for specific contaminants in food. This regulation covers several contaminants, including mycotoxins, heavy metals, chloropropanol, PAHs, dioxins, and PCBs. Traceability of seafood and seafood exported to the E.U. from January 1, 2005, with the deadline of January 1, 2010, and Traceability for wild-caught seafood products (IUU - illegal fishing, unreported) (E.C, 2001).

3.3. Challenges for Vietnam's seafood export industry facing with EU regulations

Illegal, Unreported and Unregulated (IUU) Fishing

In recent years, Vietnam has experienced issues with its food safety management system, the physical conditions of fish distribution stations, and the quality of fish distributors inside domestic distribution chains (Davies, Luu, & Dunne, 2017), which path to the infringing of IUU regulations. The IUU is defined as illegal, unreported, and unregulated fishing (International Plan of Action to Prevent, Deter and Eliminate IUU Fishing (IPOA IUU)). The EU Regulation to prevent, deter and eliminate illegal, unreported, and unregulated fishing (IUU) entered into force on January 1, 2010. This regulation includes three standards for seafood imported into the EU (E.C, 2021). The first is illegal fishing, fishing vessels in waters where fishing is illegal or prohibited. Fishing vessels that are not licensed to fish or violate national and international fishing regulations are also included in the above group. Next, IUU stipulates that fishing activities should be reported to the authorities to comply with domestic and international laws. The final element requires fishing vessels to fly the flag of a particular country and not to over-fish, catch juveniles or devastate an area's

fisheries. In addition, the EU believes that overfishing in one sea can affect the ecology of other seas, thereby affecting the fishery resources of this area.

In October 2017, Vietnam's seafood industry was issued a yellow card by the European Commission (E.C.) IUU for illegal fishing practices IUU. In order to remove the E.C.'s IUU yellow card, in 2017, the Fisheries Law was born, along with a series of different efforts based on the E.C.'s request to remove the IUU yellow card. Many provinces and cities simultaneously deployed synchronous solutions, focusing on implementing four recommendations of the E.C., including that Vietnam's sea fishing fleet does not meet standards, ensuring conditions for participating in exploitation: At seas, such as the mismatch between the size of the ship and the actual resources at sea; The system of inspection and supervision of fishing activities at sea for fishing vessels is too lacking and inefficient; Lack of a system to confirm the origin of seafood caught at sea, leading to the fact that most of the seafood caught by fishermen is of unknown origin; There is also a situation where Vietnamese fishers exploit and steal seafood in the waters of other countries.

From 2012 up to 2020, in Southeast Asia, while Thailand and the Philippines have removed the "yellow card," Vietnam has not yet been revoked by the EC. The EC said that Vietnam still has illegal fishing practices, especially fishing vessels violating foreign waters, and the control of the origin of fishery products from fishing is still inadequate. If IUU issues are not resolved, Vietnam will be identified as a non-cooperative country and may be subject to a "red card" measure. Worryingly, when being "yellow card," 100% of seafood shipments originating from Vietnamese catches are inspected when exporting to the European market (EU). In applying the "red card" measure, all fishery products from the catch will be banned from being exported to the EU. Since the EU is a credit market, other markets may apply similar measures to Vietnam's seafood exports (VASEP, 2021).

Food hygiene

Governments authorize and implement sanitary and phytosanitary (SPS) measures to regulate food safety, plant health, and animal health issues and prevent the spread of exotic pests and illnesses (Cuong, Mai, Hieu, Phuong, & Henson, 2013). E.U. regulations on food hygiene cover all stages of production, processing, distribution, and placing on the market for all food intended for human consumption. In recent years, Vietnam's seafood export industry faced problems with those regulations, especially the antibiotic residues in seafood products. The E.U. has been a challenging market for Vietnam's exporting seafood because of its stringent SPS standards. E.U. rules and regulations prohibit the use of ten antibiotics in the seafood sector (zero residues is permitted) and set maximum residual limits (MRL) for the use of ten other antibiotics. Some of these antibiotics impair human health and poison the environment. As a result, food imported into the E.U. must be rigorously inspected for antibiotic or chemical residues (under E.U. regulation No. 96/23). The use of food additives in food and seafood processing is likewise restricted in the E.U. (Truong, 2006). In recent years, Vietnam seafood export products to EU has been declined several times due to “the lack of responsibility for SPS matter” (Hagerman & Jones, 2013)

The E.U. has warned about antibiotic residues in seafood products in Vietnam various times in recent years. According to the Department of Agriculture, Forestry and Fisheries Quality Management, on May 13, 2016, the General Department of Health and Food Safety (DG-SANTE), the European Commission (E.C.) issued a circular Areas(2016)2253381 sent to the Department to notify the Vietnamese side that it has not been able to overcome the abuse of antibiotic chemicals in aquatic products effectively (SPS, 2016). The E.U. has announced that Vietnamese seafood processing facilities will be removed from the list of seafood processing facilities allowed to import into this market if the shipment of seafood is exported. This school is warned of banning antibiotic chemicals specified in Annex 2, E.U. regulation No. 37/2010. In addition, on May 24, 2016, the E.U. competent authority issued a warning document No. 16-814 to E.U. member countries about the unusual death of fish in Vietnam and suggested that the countries strictly control the batches of fish. Seafood products imported from Vietnam (SPS, 2016). Previously, at the end of April 2016, NAFIQAD also informed that the E.U. warned that many seafood export shipments of Vietnam did not guarantee food safety. These are mainly products such as Frozen pangasius products with unsatisfactory organoleptic quality (with an Ammonia smell in the product) and in products containing Sodium carbonates (E 500) are not allowed to be used, frozen pangasius products containing Sodium Erythorbate (E 316) are not allowed to be used; canned tuna products due to Histamine criteria; swordfish products due to the mercury content (SPS, 2016).

3.4. Solutions of Vietnam

In order to overcome IUU's "yellow card", several solutions have been practiced.

On May 28, 2017, the Prime Minister issued Official Dispatch 732/CD-TTG on preventing, reducing, and stopping Vietnamese fishing vessels and fishers from illegally fishing in foreign waters in an effort for the E.C. to delay the application of a yellow card to Vietnam's exploited seafood. Right after Vietnam's seafood was yellow carded, on November 21, 2017, the National Assembly passed Law No. 18/2017/QH14 regulating fisheries activities; rights and obligations of organizations and individuals engaged in fisheries activities or related to fisheries activities; State management of fisheries (from now on referred to as the Law on Fisheries 2017), effective from January 1, 2019. The Fisheries Law 2017 specifically legislates contents related to IUU regulation, including recommendations from the European Commission. On November 23, 2017, the Ministry of Agriculture and Rural Development issued Decision No. 4840/QD-BNN-TCTS approving the plan to implement several urgent solutions to overcome the warning of the European Commission on mining. Illegal, unreported, and unregulated mining (Tuyen, 2017).

After more than two years of efforts to implement measures to remove the E.C.'s yellow card, Vietnam has completed the legal framework, including Law on Fisheries 2017; 2 Decrees, 1 Decision of the Prime Minister; 8 Circulars of the Ministry of Agriculture and Rural Development guiding the Law on Fisheries... Along with that, the Vietnam Association of Seafood Exporters and Producers (VASEP) has established the IUU Executive Board, in collaboration with 28 provinces, coastal cities, businesses, and

fishermen join hands with the State agency to overcome the IUU yellow card in the shortest time, proceed to implement a long-term program against IUU fishing, maintain the reputation and market for seafood products for export of Vietnam. Up to now, there have been 62 enterprises participating in the program "Seafood enterprises committed to combating IUU fishing" with the commitments: Only purchase seafood raw materials from legally fishing vessels with export origin. Clear origin, import only caught seafood with the legal fishing origin; resolutely do not buy seafood from fishing vessels that illegally catch, exploit without permits, do not log and do not report according to regulations, fishing with prohibited fishing gear; say no to rare seafood species, catches of smaller sizes than regulated. Especially, on March 11, 2021, The strategy for the development of Vietnam's fisheries by 2030 with a vision towards 2045 No. 339/QD-TTg was approved by the Prime Minister, which provides specific strategies to improve and develop Vietnam's seafood industry in different fields.

About enterprises, in four years (September 25, 2017 - October 23, 2021), Vietnam Association of Seafood Exporters and Producers (VASEP) and the seafood business community have maintained four groups of activities: Commitment activities Against IUU fishing by enterprises, the working group, proposes and gives suggestions on amending legal documents, cooperation activities of the parties, international relations, and communication. In particular, there were 62 seafood processing and exporting factories participating in the commitment to combat IUU, especially those in the VASEP Tuna club, which made great contributions to the program's strength. VASEP has released the "White Book on Efforts against IUU Fishing in Vietnam" and produced tens of thousands of leaflets to propagate to fishermen, captains, and businesses about IUU fishing (Giang, 2021)

From October 2017 to now, over 300 television products, over 300 radio products, and over 700 paper and electronic articles related to IUU fishing have been published by Vietnamese mainstream media. Downloading and reporting; 5,000 thousand propaganda books on the 2017 Fisheries Law and nearly 60,000 propaganda leaflets about IUU to distribute to fishers in 28 coastal provinces and cities. (Lan, 2021).

In order to avoid the E.U. Competent Authority gradually eliminating enterprises on the list of allowed exports to this market, the Agro-Forestry-Fisheries Quality Management Department has issued Official Dispatch No. 1041/QLCL-CL1 dated May 30, 2016, sent to seafood processing enterprises alternatively, producing in the E.U. and relevant units to implement necessary control measures for antibiotic chemicals fully. In order to avoid being taken off the list of E.U. exports to this area, seafood processing facilities need to take samples for inspection before exporting to the E.U. proactively. Up to now, there have been more legal efforts to prevent the abuse of antibiotics in seafood exports, including Official Letter No. 952/QLCL-CL1 on developing MRPL regulations for antibiotic chemicals. In fisheries, Official Dispatch No. 966/QLCL-CL1 dated May 30, 2019, on VASEP's action plan on antibiotic chemicals until 2020.

4. Discussion and Conclusion

4.1. Recommendations

It can be seen that there are many problems in the exploitation, processing, and export of aquatic products, standing in many different aspects. The responsibility still largely rests with the government, but the role of business cannot be overlooked. Based on the actual situation, it can be seen that Vietnamese seafood still faces the following problems, sorted by level of importance:

- Removing the IUU yellow card.
- Ensuring food hygiene and safety according to EU standards.
- Applying green business strategy.
- Promoting Vietnamese branded products.

1. Vietnamese government needs to take stricter measures to remove the IUU yellow card. The Stations and the Information and Monitoring System need to be upgraded and operated 24 hours daily. It is necessary to ensure that monitoring equipment is fully installed on fishing vessels, storing information on the system, and sharing data agencies between localities. Functional forces such as the Navy, Coast Guard, Inspector need to link and coordinate in inspecting and reviewing violating fishing vessels, reporting and storing information on time to issue sanctions. For the European Commission, in addition to the efforts shown by actions, the government needs to have dialogues to clearly state Vietnam's determination to ensure safe exploitation as the top priority. For example, Thailand once declared "anti-IUU fishing" as an item on the national agenda in the reform process (Kadzak & Linke, 2021). Vietnam also needs more strong statements about the country's determination to fight IUU fishing. It is necessary to actively mobilize, negotiate and report IUU violations to the EC to remove the yellow card as soon as possible.

2. Local authorities need to propagate and guide fishers about legal fishing. Accordingly, it is necessary to clarify the impact of the IUU yellow card on Vietnam's exports, and if illegal fishing continues to happen again, it will not be able to remove the card, affecting the entire seafood industry of Vietnam. There should be direct working sessions with fishers, raising self-discipline, self-monitoring, raising awareness about the importance of safe fishing, analyzing the harmful sides of illegal fishing. Next, it is necessary to guide and help fishers use cruise monitoring devices and sanctions when intentionally disconnecting the device. In addition, Sub-Departments and Local Management Boards need to coordinate with relevant departments to control the situation closely. Do not license to operate and stop supporting preferential policies for boats that repeat violations.

3. Businesses need to be aware of the importance of combating IUU. Resolutely do not buy products of unknown origin, do not cooperate with illegal fishing vessels, terminate contracts, and report to local authorities if violations are detected.

4. Food safety issues need to be ensured. According to Law, appropriate authorities need to actively review, inspect, and inspect aquaculture processing and aquaculture enterprises and

adequately handle any violations. It is necessary to disseminate to businesses to understand the EU's regulations on food safety and hygiene, from growing, harvesting, processing to packaging according to international standards. Businesses should have seminars to talk about business difficulties and share experiences to avoid violations of food safety and hygiene.

5. Encourages businesses to follow green business strategies. Accordingly, the state needs to organize training sessions to propagate the benefits of this strategy, reduce/exempt taxes for products with green materials, products with manufacturing processes—green, products applying green technology. Central and local agencies also need to listen to the difficulties and barriers of enterprises when applying green technology to production. Businesses also need to update with the trend of green business, improve the competitiveness of products in the international market.

6. It is necessary to promote Vietnamese brands abroad actively. The promotion is generally only at a trim level of private brands. It is necessary to promote the national brand vigorously. Taking Japanese Matcha or Korean ginseng as examples, we need to promote the product under the name of the country, creating advantages for not only one but also all seafood originating from Vietnam. However, this is not a short-term problem. It is necessary to ensure from the stage of packaging, packaging design, and branding of "Vietnamese seafood" in the international market while diversifying markets, increasing export turnover in potential markets, such as Bulgaria, Estonia, Lithuania and Sweden.

4.2. Conclusion

Through the studies presented above, it is possible to see the opportunities and challenges of Vietnamese seafood in the EU market. With the successful signing of the EVFTA, the export of seafood to the EU market will have many advantages and prospects in the future. In addition, other major markets such as the UK or Japan, Korea, and ASEAN all have agreements beneficial to Vietnam, promoting exports and increasing the competitiveness of Vietnamese origin products in the international market. In 2022 - 2023, it is predicted that the fishery industry will gradually recover when the vaccination is completed, bringing the country to the "new normal" state. Demand in the markets increased, prices rose again. The main distribution channel of seafood is still the service industry, so when the epidemic situation stabilizes, the demand for seafood will increase.

However, in the immediate future, due to the complicated development of the COVID-19 situation, seafood exports will still face difficulties due to the affected supply chains; aquaculture businesses are facing many problems in terms of labor and materials. In addition, the demand of the markets decreased, so the price of the product also decreased. Accordingly, in October, the price of raw shrimp and the price of raw fish decreased by 12-14% compared to the same period last year (Chi, 2021). The epidemic's impact on the global economy, including Vietnam and its partners, is weighty, so the growth and recovery of the economy in general and the seafood industry, in particular, will not be as expected.

In addition, it can be expected that the consumption habits of the EU market will experience some changes during the pandemic. In the context of spending cuts and social

distancing, aquatic products with average prices are more popular, while frozen and convenient canned products are popular. At the same time, the demand for high-priced items tends to decrease. However, other aspects such as origin and environmental friendliness remain unchanged because seafood sold in the EU market has already passed the strict regulations of IUU and food hygiene. Therefore, if Vietnamese exported seafood is expected to meet the requirements of the EU market, Vietnam needs to pay more attention to food safety and hygiene as well as sustainability. Aquaculture businesses are not proactive and still face many barriers in applying green business models. The listed difficulties in implementing enterprises' eco-friendly business strategies (Binh, 2021), based on shrimp exporting enterprises in Vietnam In Vietnam, can be mentioned as the weakness of enterprises in deploying and applying technology, the lack of attention from the government, the difficulty in the lack of information and knowledge on green business strategies. Shrimp accounts for the most significant proportion of Vietnam's total seafood export turnover.

Last but not least, within the EU, Vietnamese seafood is still relying on large markets, such as the Netherlands, Germany, Italy, etc. The three markets mentioned above accounted for 52.5% of the total export turnover of Vietnamese seafood to the EU. It is necessary to promote Vietnamese seafood consumption in other countries to increase total export turnover and diversify markets. Each country will have a different economic, political, climate, consumption trend, and there are significant risks to depending too much on specific markets. Diversifying the market also helps products with Vietnamese brands become more popular while also increasing the competitiveness of products.

Abstract

In response to salinity intrusion in Mekong Delta, infrastructure such as coastal sea dykes and sluice gates have been identified as a viable strategy for salinity intrusion risk reduction. However, many doubt the possibility of preventing salinity of these works. To gain the public support, it is important to understand the public perceived efficacy of the sluice gates system. This study aims to find out the (1) public awareness of salinity intrusion and (2) their perceived efficacy of sluice gates system in Kien Giang province. A survey of 213 households in Kien Giang province showed that the perceived efficacy of the sluice gates of the farmers is influenced by the location of the farmers (whether they are protected by a large sluice gate or not), the perceived impact of salinity intrusion on income and water for production and the trust in state's measures. This study will provide insights about how to gain the support from the public for large project by the government in response to salinity intrusion.

Keywords: *perceived efficacy, salinity intrusion, sluice gates, Kien Giang*

1. Introduction

The Mekong Delta is the southernmost region of Vietnam and is one of the important regions of the country. The Mekong Delta covers approximately 12 % of the national area and is home to one-fifth of Vietnam's population. The region provides more than 50 percent of Viet Nam's staple food crop production and marine fisheries and aquaculture, worth up to USD 2.7 billion annually (WWF, 2016). The regional GDP growth rate for the Mekong Delta averaged 6.95 % during the years 2016-18, close to the national average over the same period (Tran, 2019).

The Mekong Delta is the downstream part of the Mekong River bordering the sea, with low and fairly flat terrain with two large low-lying areas, Dong Thap Muoi and Long Xuyen Quadrangle. Along with the main streams - Tien and Hau rivers, the Mekong Delta has an interlaced system of canals, creating favorable conditions for saline intrusion due to

tides bringing salt water deep into the river and inland areas, especially during the dry season, when the flow from the upper Mekong River is low.

Due to its geographical location, the Mekong Delta is influenced by tides from both the East and West seas. During the dry season, when the flow of water in the upstream decreases, the tide strongly affects the upstream and the inland canal system, leading to deep salinity intrusion in the river and in the field. Therefore, salinity intrusion in this area is a complicated process that depends on the magnitude of the upstream flow during the dry season and the amount of sea level increase. Over 50% of the Mekong Delta area (39,330 km²) is saline, including the provinces of Long An, Tien Giang, Ben Tre, Tra Vinh, Soc Trang, Bac Lieu, Ca Mau and Kien Giang (NASATI, 2016). Increasing salinity levels in the Mekong Delta have significantly affected agricultural production, especially for crops with a low tolerance to salinity. Salinity intrusion is one of the most significant threats in the Mekong Delta, especially in the context of changing climate and rising sea level, leading to negative impacts on the livelihoods of local people.

In response to salinity intrusion, Mekong Delta farmers have adopted various strategies based on their own knowledge of farming and/or based on neighbour suggestions. The most popular non-engineering adaptation measures were changes to farming systems through altering planting times, adjusting planting techniques, shifting to other crop varieties, changing irrigation schedule, diversifying income sources reinforcing safety for humans and assets and other measures (Hoa Dang, 2014; T. Dung Khong, 2019). Alternatively, infrastructure such as coastal sea dikes and sluice gates have been identified as a viable strategy for salinity intrusion risk reduction.

Cai Lon - Cai Be sluice gate project is the largest sluice system in the Mekong Delta of Vietnam, with the cost of VND3.3 trillion (equivalent to US\$142 million). The main functions of the infrastructure include controlling water sources for cultivation and fishery production in the beneficiary area of 384,120 hectare in five provinces including Kien Giang, Hau Giang, Ca Mau, Bac Lieu and Soc Trang. It contributes to the supply of fresh water in the dry season and to reduce the flood in rainy season. The sluice gate and the west sea dyke also form an infrastructure system to proactively respond to climate change, sea level rise and natural disaster and to reduce inundation due to land subsidence. On February 5, 2021, Cai Be sluice gate was put into operation, promptly preventing salinity intrusion for Kien Giang province. Cai Be sluice gate would save VND 12 billion for the locality in the dry season 2020-2021 as otherwise 100 temporary dams must have been developed. Cai Lon sluice gate has been operating since March 2022.

Lack of public support for adaptation can present significant barriers for implementation. A systematic review found that for coastal climate change adaptation, hard protection options were often the most frequently preferred, likely due to a desire to maintain current shoreline, for the protection of recreational spaces and private property, and a perceived efficacy of hard protection options (Malette, 2021). In the case of Cai Lon - Cai Be sluice gate in particular and measures responding to salinity intrusion in the Mekong Delta in general, there is a lot of controversy. Many doubt the possibility of preventing

salinity of these works¹. Thus, to gain the public support, it is important to understand the public perceived efficacy of the sluice gates system. This study aims to find out the (1) public awareness of salinity intrusion and (2) their perceived efficacy of sluice gates system in Kien Giang province. This study will provide insights about how to gain the support from the public for large project by the government in response to salinity intrusion.

2. Literature review

Community's preferences for measures to respond to weather events have been studied in literature. Factors affecting the preferences for adaptation measures in coastal area are various, ranging from cognitive processes (e.g., perception of risk, psychological distancing, worldviews, beliefs), to social or cultural aspects (e.g., social ties, social norms, cultural traditions), to contextual aspects (e.g., location, demographic characteristics, previous experiences), to appraisal of the adaptation (e.g., financial, ecological, aesthetic benefits and concerns). However, several factors are more complex and multidimensional. For example, place attachment has aspects that are strongly emotional, cultural, social, and cognitive, and is also connected to appraisal considerations (for example, livelihood considerations). In addition, the conceptual boundaries of these factors are fuzzy, and some terms are used interchangeably (e.g., beliefs, values, worldviews). Perception of risk, place attachment, and financial considerations were the three most frequently occurring. It is commonly assumed that risk perception is directly influential on climate change beliefs, support for policies, or adaptive behaviours (Leiserowitz, 2006; Singh, Zwickle, Bruskotter, & Wilson, 2017). Some found a significant effect in either a positive or negative direction (Dachary-Bernard, Rey-Valette, & Rulleau, 2019; Milman, Warner, Chapman, & Short Gianotti, 2018; Rulleau, Rey-Valette, & Hérivaux, 2015), while others found no or mixed effect (Shao, Xian, Lin, & Small, 2017; Song & Peng, 2017). Similarly, demographic factors were one of the most reoccurring themes, but the effect of these factors is not consensus. Some found that age was important (Apine, 2011; McMichael, Katonivualiku, & Powell, 2019), while others found no differences (Treuer, Broad, & Meyer, 2018). The variable 'location' was found to have inconsistent effect (Malette, 2021). In Vietnam, farmers' preferences for sea dykes as a long-term public adaptation measure are affected by willingness-to-pay, housing value impact, impact on water supply for agricultural activities, households' habitation environment and regional economics were significant determinants of farmers' preferences. (T. Dung Khong, 2019)

The perceived efficacy of public goods are assessed in some studies. The Protection Motivation Theory and the extended Theory of Planned Behavior are used widely to identify the influencing factors (Jou & Mariñas, 2022; Kurata et al., 2023; Prasetyo, Castillo, Salonga, Sia, & Seneta, 2020). Applying the Theory of Planned Behavior, the perceived behavioural control, attitude towards behaviour and subjective norms have positive effect on perceived effectiveness (Kurata et al., 2023). Perceived efficacy can also be impacted indirectly by perceived vulnerability and perceived severity (Prasetyo et al., 2020). Perceived government response had significant effects on perceived effectiveness (Jou & Mariñas, 2022).

3. Method

Data collection

Data were collected by direct interview method with both rice farming and shrimp-rice farming households. For comparative analysis purpose, the survey focused on the farms within the protected area of Cai Lon - Cai Be sluice gates (in Binh An Commune, Minh Hoa Commune of Chau Thanh District and in Hung Yen Commune, Dong Yen Commune of An Biên District) and also the farms outside of the protected area of Cai Lon - Cai Be sluice gates (in Binh Giang Commune, Linh Huynh Commune and Son Binh Commune of Hon Dat District). The survey had a total of 213 respondents, consisting of 50 rice farming households and 55 shrimp-rice farming households in the protected area of Cai Lon - Cai Be sluice gates and 70 rice farming households and 38 shrimp-rice farming households outside of the protected area of Cai Lon - Cai Be sluice gates. The content of the questionnaire included household information, production, expenditure and income information, perception of salinity intrusion, the private adaptation measures and assessment of public measures to salinity intrusion.

Before the official survey was implemented, the questionnaire was pilot tested with 10 household-heads to ascertain whether or not farmers could understand the questions and information provided. The pilot also had the role of training the enumerators on the questionnaires. The enumerators for the study were carefully chosen from the staffs of local Agricultural Extension Agencies.

Data analysis

Likert scales are widely employed to collect respondents' attitudes and opinions. Likert scale is simple to construct and likely to produce a highly reliable scale. Besides, from the perspective of participants, it is easy to read and complete. To date, a number of risk perception and attitudinal studies have also adopted/modified Likert-scale measurement in their field research, e.g. Hoa Dang. (2014), Hoa Dang (2014), T. Dung Khong (2019). The seven-point scale appears to be widely preferred because it contains a neutral position that enhances measurement quality (Nowlis, 2002) Hence, the dimensions in this analysis were measured based on the seven-point Likert-type scale.

The model of perceived efficacy of farmers of the sluice gates can then be expressed as follows:

$$PE = \beta_1 + \beta_2 H + \beta_3 \text{Location} + \beta_4 \text{Impacts} + \beta_5 \text{WTP} + \beta_6 \text{Trust} + \varepsilon \quad (1)$$

where PE represents perceived efficacy of farmers of the sluice gates in response to climate change; H is the group of household characteristics including gender, age, level of education, household size and monthly income; Location represents the districts where the household lives which is 0 if the farmer lives in Cai Lon - Cai Be sluice gates' protected area (Chau Thanh and An Bien district) and is 1 if the farmer lives in Hon Dat which is outside the protected area of Cai Lon - Cai Be sluice gates; Impacts are the impacts of salinity intrusion on the farmers' living condition, which are reducing income, affecting the water

for production, affecting the domestic water, reducing crop production, reducing aquaculture production, affecting human health, affecting environmental health, reducing value of assets and causing worry of damage; WTP is the willingness to pay per hectare per year for better sluice gates; and Trust captures the trust of the farmers on the states' measures. Multicollinearity is checked with the variance inflation factor (VIF) values. The results of VIF values show no significant signs of this problem.

4. Results

4.1. Demographic characteristics of the respondents

The descriptive statistics of sample is presented in Table 1. The mean age of the respondents in Chau Thanh and An Bien is 54 (standard deviation is 12.72) while in Hon Dat is 49.2 (standard deviation is 12.74). The female is 29, accounts for 13.6% and male is 177 or 86.4% of the respondents. Only 10 people interviewed are single, the others are married. Most of the households in the survey are of Kinh and Khmer ethnicity. The average household size is 4.85 and 4.23 in Chau Thanh & An Bien and Hon Dat respectively. The education level is low. 25.1% finished primary school and 19.7% reached secondary school, which are the majority of the respondents. 170 households in the sample have the annual income of less than VND 300 mil. There are 15 households which have the annual income of more than VND600 mil., all of which are in Hon Dat. They are the owners of industrial shrimp farms.

4.2. Perception of salinity intrusion

Each farm household head was asked to assess the impacts of salinity intrusion in recent years, ranging from 1 = not severe at all to 7 = extremely severe. The results reveal that negative influences on income, water for production and rice production are the most concern of the farmers. There are 44 missing observations in the question on the impact of aquaculture production as they are the rice farmers. Fewer were concerned about impacts on daily water supplies. Salinity is necessary for aquaculture production, and the water for shrimp farmings can be controlled by the farmers, therefore the impacts on aquaculture production is the less concerned issue.

Table 2. Perception of salinity impacts

	Reducing the income	Reducing value of assets	Affecting the water for production	Affecting the domestic water	Reducing crop production	Reducing aquaculture production	Affecting human health	Causing worry of damage	Affecting environmental health	Other impacts
Mean	4.90	4.27	4.95	4.07	5.23	2.64	3.38	4.60	3.98	4.13
Median	5.00	5.00	6.00	4.00	6.00	1.00	4.00	5.00	4.00	4.00
Mode	7	1	7	1	7	1	1	7	1	4
Std. Deviation	2.180	2.152	2.101	2.216	2.104	2.069	2.102	2.198	2.097	1.586

The question on the cause of salinity intrusion was asked with the answer ranging from 1 = extremely disagree to 7 = extremely agree. The survey shows that sea level rise is considered the main reason for salinity intrusion with the mean value of 6.03. Drought rank the second important cause as assessed by the respondents with 93 chose the level 7 for their answer. Sea level rise and drought are among the signs of climate change, thus it can be seen that the farmers in the survey area are clearly aware of the change in the climate in recent years.

Table 3. Perception of the cause of salinity intrusion

	N	Minimum	Maximum	Mean	Std. Deviation
Sea level rise	213	1	7	6.03	1.405
Lack of fresh water from upstream	212	1	7	5.21	2.009
Drought	212	1	7	5.64	1.748
Reduced water reserved	210	1	7	4.61	1.889
Increasing demand for water	209	1	7	4.24	2.046

81 people (38%) of the respondents forecast that in the next 3 years, salinity intrusion in the area would increase. They explained that the trend of salinity intrusion had been increasing over time. 21.6% had the opposite answer because they assessed that the salinity intrusion was of the most severe in the year 2019-2020, thus in the future it would decrease. 38 respondents thought the level of salinity intrusion would unchange and 31 said that they did not know. 17 people (8%) had no answer.

Table 4. Forecast of salinity intrusion in the next 3 years

	Frequency	Percent
I don't know	31	14.6
Unchanged	38	17.8
Decrease	46	21.6
Increase	81	38.0
Total	196	92.0
Missing	17	8.0
Total		100.0

4.3. Perceived efficacy of the sluice gates

The perceived efficacy of the sluice gate system in Kien Giang is assessed by 5 questions: (1) The sluice gate system supplies sufficient water to meet the demands of agricultural production; (2) The sluice gate system supplies water at the right time for each crop; (3) The sluice gate system supplies water of good quality for each crop; (4) The sluice gate system is operated strictly as scheduled before; and (5) The sluice gate system is operated in the way that ensures the balance between different water users (i.e., rice farmers and shrimp farmers). The answer ranges from 1 = extremely disagree to 7 = extremely agree. Table 4 shows that the mean of the answer between two districts are relatively equal except the statement (4). The independent sample T-test also confirms that there is a significantly difference between the answers of the Chau Thanh and Hon Dat farmers in statement (4).

Table 5. Perceived efficacy of the sluice gate system in Kien Giang

	Location	Mean	Std. Deviation
The sluice gate system supplies sufficient water to meet the demands of agricultural production	Hon Dat	5.61	1.528
	Chau Thanh & An Bien	5.89	1.539
The sluice gate system supplies water at the right time for each crop.	Hon Dat	5.64	1.557
	Chau Thanh & An Bien	5.81	1.631
The sluice gate system supplies water of good quality for each crop	Hon Dat	5.64	1.633
	Chau Thanh & An Bien	5.90	1.536
The sluice gate system is operated strictly as scheduled before.	Hon Dat	6.01	1.370
	Chau Thanh & An Bien	5.52	1.712
The sluice gate system is operated in the way that ensures the balance between different water users (i.e., rice farmers and shrimp farmers).	Hon Dat	5.67	1.626
	Chau Thanh & An Bien	5.58	1.606

4.4. Trust in state's measures in response to salinity intrusion

In response to salinity intrusion, the state has a variety of measures. They include forecasting and warning the salinity level, land use planning; restructuring crop and cultivation models, in particular selecting of plants and crops which can be tolerant to various salt limits; applying advanced cultivation techniques such as less water irrigation practices; and salinity intrusion control structures measures including dykes, dams and sluice gates. To investigate the farmers' trust in public measures, three statements were used which are (1) State and local authorities know what they have to do to response to salinity intrusion; (2) The government salinity warning system is reliable; and (3) Public adaptation measures are

very effective. The survey shows that the local farmers' trust in public measures are of very high level with approximately 90% of the respondents agreed (choosing the answer 5 to 7 in a 7-point scale) with each statement. The means are 6.3, 6.39 and 6.31 for statement (1), (2), (3) respectively.

Table 6. Trust in state's measures

	Minimum	Maximum	Mean	Std. Deviation
State and local authorities know what they have to do to response to salinity intrusion	2	7	6.30	1.086
The government salinity warning system is reliable	1	7	6.39	1.078
Public adaptation measures are very effective	1	7	6.31	1.199

Chronbach's Alpha coefficient of these three variables is 0.709. KMO is 0.635 and the total variance extracted was 63.87%. The factor loading coefficient of each observed variable showing all the factors is greater than 0.5. Thus, these three variables can be extracted as one components by factor scores.

4.5. Factors of influence perceived efficacy of the sluice gates

The Reliability Analysis show that Chronbach's Alpha coefficient of the five variables expressing the perceived efficacy is 0.872, thus, the these measurement variables have reliability and are used in factor analysis. In the Exploratory factor analysis, KMO reached 0.822. The KMO index of the research model is greater than 0.5, showing that the application of exploratory factor analysis here is completely appropriate. The total variance extracted was 66.196%. The factor loading coefficient of each observed variable showing all the factors is greater than 0.5, showing that the observed variables all show the influence with the factors that these variables represent. The dependent variable is calculated as the factor scores.

Table 7 provides the final results of the linear regression analysis which were conducted for factors affecting the public perceived efficacy. The table shows the variables that are significant (p -value < 0.1) in explaining the variations in the perceived efficacy of the sluice gates. The variables explain the variance in perceived efficacy of the sluice gates by 28.4%, which indicates a good fit for these types of models. The results show that the variables of location (Hon Dat vs. Chau Thanh & An Bien), impact of reducing income, impact of affecting water for production and trust in state's measure have a statistically significant influence on the perceived efficacy of sluice gates. A VIF less than 5 indicates a low correlation of that predictor with other predictors, thus collinearity is not an issue in this model.

Table 7. Regression of factors affecting perceived efficacy of the sluice gates

Model	Standardized Coefficients	t	Sig.	Collinearity Statistics	
				Tolerance	VIF
1 (Constant)		-.293	.770		
Age	-.092	-1.043	.300	.773	1.294
Gender	-.073	-.839	.404	.795	1.258
Education level	.054	.610	.543	.778	1.286
Household size	.081	.935	.352	.793	1.260
Annual household's income	.009	.101	.920	.736	1.358
Location	-.207**	-2.285	.024	.731	1.368
Reducing the income	.380**	2.199	.030	.202	4.957
Affecting the water for production	-.301*	-1.767	.080	.208	4.818
Affecting the domestic water	.222	1.555	.123	.294	3.396
Reducing crop production	-.041	-.271	.787	.257	3.889
Reducing aquaculture production	-.078	-.884	.379	.778	1.285
Affecting human health	.030	.238	.812	.370	2.699
Affecting environmental health	.199	1.347	.181	.275	3.631
Reducing value of assets	-.006	-.039	.969	.222	4.497
Causing worry of damage	-.193	-1.230	.221	.245	4.086
WTP per hectare per year	.049	.583	.561	.859	1.164
Trust in state's measures	.424***	4.983	.000	.831	1.203

The positive and significant coefficient of Location in the model implies that farmers in Chau Thanh has higher perceived efficacy of the sluice gates. Chau Thanh and An Bien's agricultural area is mostly protected by Cai Lon - Cai Be sluice gate. When the survey was conducted, the Cai Be sluice gate was finished and put into operation, which helped the local farmers in Chau Thanh and An Bien avoid the impact of salinity intrusion in 2021. Thus, the community in the protected area of Cai Lon - Cai Be have the higher perceived efficacy of the sluice gates. Among the perceived impacts of salinity intrusion, there are two variables that significantly influence the perceived efficacy of the sluice gates: reducing the income and affecting water for production. The coefficient of "reducing the income" is positive implies the higher concern of local farmers on reducing the income, the higher perceived efficacy of the sluice gates. However, the coefficient of variable "affecting the water for production" is negative with statistical significance show that the higher concern on impacts of salinity intrusion on water, the less perceived efficacy of the sluice gates. The shrimp farming households need saline water for production. In some parts in Hon Dat district where there are large industrial shrimp farms, the sluice gates are close all around the year or open in only few days, leading to lack of saline water for shrimp farming. These farmers have the low expectations of the sluice gates, which can explain the negative influence of the variable "affecting the water for production" on the perceived efficacy. The variable "trust in state's measures" have positive

coefficient, which is consistent with the result of Jou and Mariñas (2022) that perceived government response had significant effects on perceived effectiveness.

5. Policy implications and conclusion

Saline intrusion is a natural disaster that greatly affects the lives and livelihoods of people in the Mekong Delta. In the context of increasing climate change, saline intrusion tends to become severe. In addition to "soft" adaptation measures, hard-structured measures solutions such as sluice gates are built widely in the Mekong Delta. However, the operation of these works has not yet met the needs of the people in ensuring fresh and salt-water sources for rice cultivation and aquaculture. Therefore, in order for people to support the construction of sluice gates, it is necessary to raise farmers' perceived efficacy of sluice gates.

The study was conducted on 213 households in Kien Giang province with two groups, one group of households protected by the largest irrigation works in Vietnam - Cai Lon - Cai Be sluice gates and the other group protected by small sluice gates. The determinants of perceived efficacy of the sluice gates are the location, the perceived impacts of salinity intrusion on reducing the income and affecting the water for production, and the trust in states' measures in response to salinity intrusion. Thus, in order to improve the perceived effectiveness of households for sluice gates, it is necessary to pay attention to the following issues: (1) improving the operating procedures of sluice gates, ensure water sources for both rice cultivation and aquaculture production; (2) enhancing the value of local agricultural products to increase the income for farmers and (3) increasing people's trust in the government's measures in response to salinity intrusion including forecasting and warning the salinity intrusion, updating the information on salinity level for farmers in the dry season and supporting the farmers in "soft" measures such as crop diversification and providing training on salt tolerance production.

Abstract

Natural essential oil production is an industry with a lot of potential in both the global and Vietnamese markets. In the general trend of global and Vietnam, the transition from traditional linear economic models to circular economic models aims at connecting economic processes, ensuring materials to be recovered, restored and regenerated, and keeping the materials in use as long as possible, Vietnamese essential oil producing enterprises should be aware of their responsibilities and seize this opportunity.

*Based on the identification of resources and environmental challenges in natural oil production, combined with expert consultation and international experiences learning, this paper proposes a number of opportunities to implement circular economy in natural essential oil production in Vietnam. Opportunities are proposed following the approach of the ReSOLVE framework (**R**egenerate; **S**hare; **O**ptimize; **L**oop; **V**irtualize; and **E**xchange) along the production value chain. The paper also makes recommendations for businesses and the Government to promote the application of circular economies in the production of natural essential oils in Vietnam.*

Keywords: *Circular Economy, Natural Essential Oil Production, Circular Economy Opportunities, ReSOLVE framework.*

1. Introduction

The traditional linear economy approach, based on the principle of *Resource Extraction* from the environment, through the process of *Production, Distribution, Consumption* and finally *Disposal* to the environment has been leading to the depletion of natural resources, increased waste and pollution, and environmental degradation.

The Global Financial Integrity Organization (GFI) estimated the demand for natural resources for human economic activity is now 1.7 times greater than the Earth's capacity. Therefore, without changing the way of development, the depletion of natural resources is inevitable. Regarding waste, it is predicted that by 2050, the total amount of plastic waste would be even more than the total volume of fish in the oceans. (Ellen MacArthur Foundation, 2016). Facing with this fact, many countries are transitioning to the Circular Economy, with the core approach is connecting endpoints to the starting points of economic processes, enabling recovered materials to be returned as inputs for activities; even restore and regenerate matter at the end of each round of extraction, production, distribution, and consumption, keeping the material in use as long as possible in the economic system.

In Vietnam, Article 142 of the Law on Environmental Protection (2020) defines the circular economy as an economic model in which the activities of design, production, consumption and service activities aim at reducing the extraction of raw materials, prolonging the product life cycle, minimizing waste generation and minimizing adverse impacts on the environment. Subsequently, the Scheme for Circular Economic Development in Vietnam (Decision 687/QĐ-TTg dated June 7, 2022) assigned the Ministry of Natural Resources and Environment to develop and issue a guiding framework for application and evaluate the implementation of the circular economy; Ministries and ministerial-level agencies are responsible for organizing the pilot application of the circular economy model to a number of industries and sectors.

In recent years, the production of natural essential oils has been introduced into Vietnam and developed rapidly, meeting the needs of domestic consumption, especially for export. By 2021, Vietnam's natural essential oil production accounted for 1.16% in quantity and 0.6% in value of the global essential oil market share (Vietnam of Essential Oils Aromas and Cosmetics Association, VOCA). In the context of global market's increasing use of natural compounds, as well as the significant advantages of tropical crops such as mint, melaleuca, lemongrass, cinnamon, anise, coriander, garlic, perilla, holy basil, eucalyptus, basil, orange, lemon, grapefruit..., the production of natural essential oil is truly a potential industry which attracting the interest of many domestic and foreign investors.

However, the production of natural essential oil in Vietnam today mainly follows the traditional linear economic model, consuming a lot of fuel and causing waste of resources and negative impacts on the environment. Some essential oil production stages in various enterprises have begun to shift toward a circular economy, but they are spontaneous, less efficient both in terms of environment and economy.

This paper aims to clarify the contents and opportunities of applying circular economy in the manufacturing of natural essential oil in Vietnam. The application of the circular economy is an essential requirement as well as opportunities to assist firms in achieving sustainable production and consumption goals, effective response to climate change, and contribute to national and global sustainable development goals.

2. Method

Desk review: study reports/ papers published in Vietnam and abroad to clarify the contents of circular economy and the practical experience in applying circular economy in the production of natural essential oils.

Collecting primary data: interviews, discussions (offline and online) with representatives of a number of natural essential oil producers in Vietnam to find out the production and business situation, current status and potential of circular economic application, the enterprise's advantages and difficulties.

Meta-analysis: to identify resource and environmental problems of current linear economic model as well as potential opportunities to apply circular economy in natural essential oil production in Vietnam, following the elements of the ReSOLVE framework.

Expert method: consult experts who are managers and/or professionals with knowledge and practical experience related to circular economy, environment and sustainable development to assist in identifying potential opportunities to apply circular economy in natural essential oil production in Vietnam.

3. Results

3.1. The concepts and contents of Circular Economy

According to Pearce and Turner, circular economy aims to overcome the limitations of the traditional linear economy by pursuing the recycling and reuse of material flows, energy, and waste in the production, consumption and disposal processes, maintaining the functions of the environmental system with respect to the economic system (David W. Pearce and R. Kerry Turner, 1990).

According to the Ellen Mac Arthur organization: "*The circular economy replaces the concept of "end of life" of materials with the concept of recovery, shifting towards the use of renewable energy, stop using of harmful chemicals that can limit reuse; shifting towards reducing waste through the design of materials, products, engineering systems and business models within the boundary of that system*". The concept of Ellen Mac Arthur is most widely recognized, referenced and used by many countries and international organizations.

Circular systems apply processes of reuse, repair, refurbishment, remanufacturing and recycling to create closed-loops for resource use in the economic system, to minimize the amount of resources used and waste generated, as well as levels of environmental pollution and emissions (P.T.T.Ha, 2020). All "waste" of one production and consumption process should be considered as raw materials/ inputs of other production and consumption processes or the production and consumption process itself, with the goal of elimination of negative impacts on the environment and regeneration of natural systems.

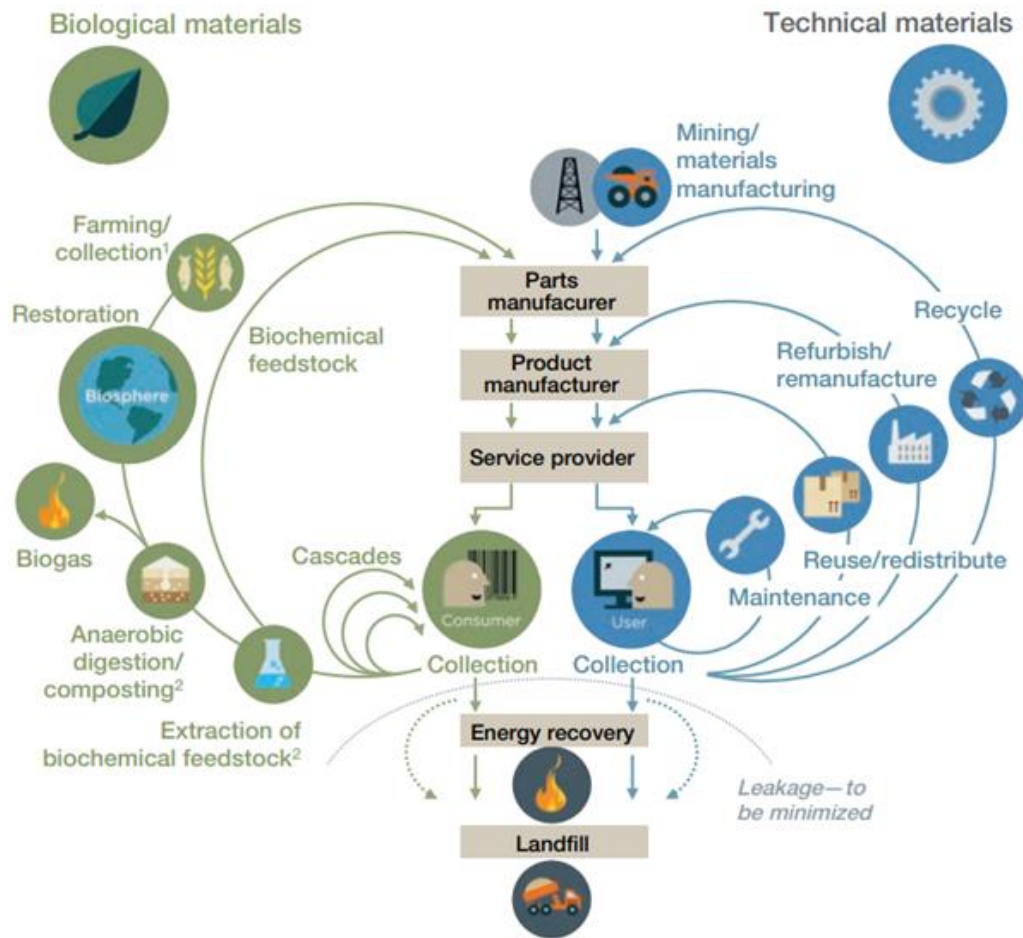

Figure 1. Closed-loops in the circular economy

Source: Ellen MacArthur (2015)

According to Ellen MacArthur Fund (EMF, 2015), the circular economy is based on 3 basic principles, including:

1, *Conservation and development of natural capital* through control with a view to the resource efficiency and the regeneration of natural systems; especially, promote the use of renewable energy.

2, *Optimizing resource returns* by circulating products and materials as much as possible in engineering and biological cycles.

3, *Improve the overall efficiency of the whole system* by minimizing negative externalities, through waste and pollution design from the very beginning of the production process.

These contents/ principles help to break the usual link between economic development and negative environmental impacts. The circular economy is not about waste treatment, on the contrary, considering waste as a resource that is misplaced, or undervalued.

According to the United Nations Industrial Development Organization (UNIDO), the implementation of a circular economy is "implementation in production and business", following the value chain approach, including activities such as: Product design towards

reducing the amount of materials used, reducing/ replacing hazardous chemicals, improving durability/ reusability /upgradability /reparability/ recyclability; Increase the recycled content in the product; Efficient use of energy and other resources; Maximize resource efficiency in production; Optimize the use of products; Allow reproduction; Regenerate biomass and recycle materials. After maximizing the material cycle, energy will be recovered from the waste so that it is not released into the environment. (Le Thanh Thao, UNIDO Vietnam 2020).

The aforementioned principles and contents of the circular economy can be presented as a framework with 6 business operations (called the ReSOLVE framework), including: (1) **R**egenerate; (2) **S**hare; (3) **O**ptimize; (4) **L**oop; (5) **V**irtualise; (6) **E**xchange.

The circular economy is a general global trend that has proven to be successful in many countries over the world, such as Sweden, Denmark, Finland, Canada, Japan, China, and Singapore...

In Vietnam, the Law on Environmental Protection 2020 (Law No. 72/2020/QH14 dated November 17, 2020) has officially mentioned “*Circular economy is an economic model in which the activities of design, production, consumption and services are aimed at reducing the exploitation of raw materials, prolonging the life cycle of products, limiting waste generated and minimizing the adverse impact on the environment*”.

Decree No. 08/2022/ND-CP of the Government dated January 10, 2022, detailing a number of articles of the Environmental Protection Law that specified the General Criteria for the Circular Economy in Vietnam (Article 138), including:

a) Reducing exploitation and use of non-renewable resources and water resources; increase efficiency in the use of resources, raw materials and materials; saving energy;

b) Extend the duration of use of materials, equipment, products, goods, and components;

c) Reducing waste generation and minimizing adverse impacts on the environment, including reducing solid waste, wastewater, and emissions; reducing the use of harmful chemicals; waste recycling, energy recovery; reducing single-use products; and green procurement.

In sum, it can be stated that Vietnam has a fairly sufficient policy and legislative framework to encourage and facilitate the implementation of the circular economy by industries, enterprises, communities, organizations, and individuals.

3.2. Natural Essential Oil Production in Vietnam and the Environmental Issues

Vietnam is located in the tropical monsoon climate zone, with rich and diverse plant resources, especially the group of essential oil plants. The number of species containing essential oils in the flora of Vietnam includes about 657 species belonging to 357 genera and 114 families (about 6.3% of the total species, 15.8% of the total genera and 37.8% of the total families). Rich families of genera and species containing essential oils are Asteraceae,

Oranges (Rutaceae), Ginger (Zingiberaceae), Mint (Lamiaceae), Camphor (Lauraceae)... Vietnam is considered one of the countries with an enormous source of essential oil plants in the world. The diversity of natural herbal raw materials in Vietnam is compared to the 'green gold mine' of the natural essential oil extraction industry.

According to statistics from the Vietnam of Essential Oils Aromas and Cosmetics Association (VOCA), there are about 300 types of plants used to extract essential oils in Vietnam, of those there are about 50 most used types namely lemongrass, incense, eucalyptus, melaleuca, mint, anise, cinnamon. Some types have recently been used for essential oil extraction but rapidly developed such as coriander, garlic, patchouli, basil, and perilla. These plants are quite easy to grow, do not take too much time to care for, and are less susceptible to pests and diseases than other plants. Therefore, the production and extraction of natural essential oils is gradually being interested in development.

Another potential source of raw materials for the natural essential oil industry is agricultural by-products from the citrus peels. According to the Department of Crop Production (Ministry of Agriculture and Rural Development), citrus trees throughout the country have continuously increased in recent years, with a high growth rate. Citrus trees are currently the group of fruit trees with the largest area and output; in which mainly oranges (about 100,000 hectares, output over 840,000 tons) and grapefruit (over 105,400 hectares, output nearly 950,000 tons). Therefore, the source of orange and grapefruit peels is discharged at citrus extraction/ juices production facilities is a lot. In addition, it is necessary to mention the source of pruned young grapefruit from gardeners or cooperatives. The pruned young fruit is also a source of raw materials for extracting essential oils.

Although the natural oil production industry has just been introduced to Vietnam in recent years, it has rapidly developed, accounting for a significant proportion of our country's export turnover. As of 2021, Vietnam has successfully exported essential oils, accounting for 1.16% in volume and 0.6% in value of the global natural essential oil market share. It can be clearly seen that Vietnam's natural essential oil production and extraction industry has been making positive changes and is an extremely potential industry.

A typical process of the traditional value chain in the production of natural essential oils from oil plants is presented in the diagram in Figure 2. The process starts with the raw materials in the oil plant growing area, then harvested and becomes raw materials for extracting essential oils in factories. The obtained essential oil will be packaged and distributed to consumers (directly used or used as raw materials for the production of food, pharmaceuticals, cosmetics, etc.). After being consumed, bottles/ containers of essential oil are often discarded along with other types of household waste.

Resource and environmental issues arise in all stages of the traditional value chain, involving both inputs and outputs of each stage.

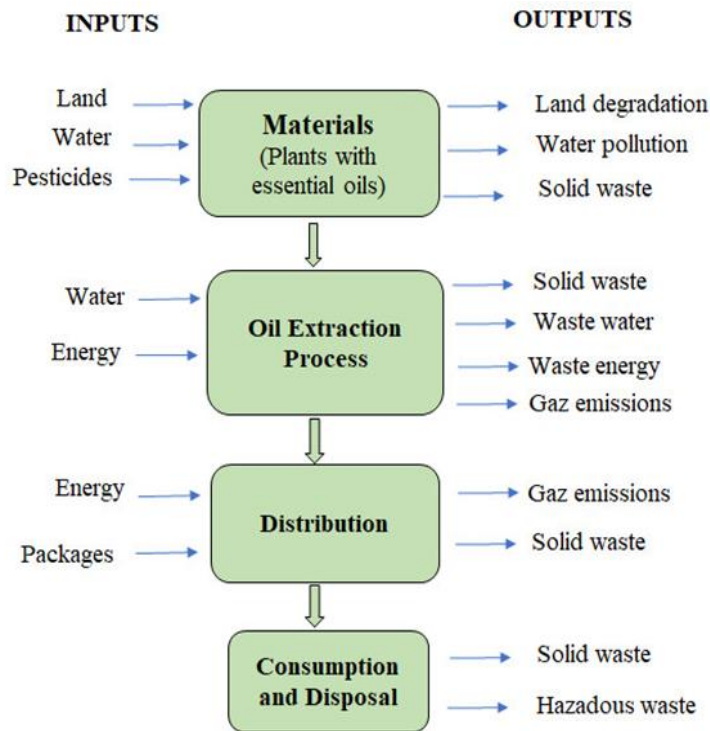

Figure 2. Major natural resource and environmental issues in traditional essential oil product value chain

Source: Compilation by the research team

In raw material growing areas: Growing raw material plants often requires quite large areas of land, using a lot of water for irrigation and fertilizers, pesticides... The improper use of pesticides, the non-guarantee of type, dose and isolation period, and sometimes the abuse of pesticides causes great harm to the environment such as: unbalance the ecosystem due to killing many beneficial natural enemies like parasitic wasps or predatory insects; cause soil pollution and land degradation if intensive farming and long-term and continuous use of pesticides causes toxic substances to accumulate gradually in the soil. The amount of chemical residue left in the soil for too long will produce a new compound, which is often more toxic than the original chemical itself. Many growing areas are currently facing poor soil conditions due to unsustainable farming.

The pesticides that have not yet penetrated into the soil will overflow in the field, canals, or through the soil and seep into groundwater; the pesticides packaging or bottles that farmers throw away in the fields, or when cleaning the pesticides containers and then pouring them into nearby water sources - causing severely water pollution, directly affecting the health of the animals that live in the water. At the same time, it seriously affects human life and health.

Solid waste - generated due to many types of materials using only one or a few parts of the plant, so the remaining parts such as stems, branches, leaves, flowers, etc. or damaged and redundant materials - are often thrown indiscriminately or burned, continue to pollute water, soil and air, emit CO₂ causing climate change impacts.

In extracting essential oil process: Raw materials are preliminarily processed, cleaned, minced and put in a pot with a lot of water. Given the fact that many production facilities still use outdated technology, simple equipment, and inefficient boilers, the consumption of water and energy inputs (electricity, wood, coal, oil, etc.) as well as the output emissions are quite large, including CO₂ emissions which cause the greenhouse effect.

It takes tens or even hundreds of a cubic meter of water and hundreds of kilograms of raw materials to produce 1 liter of lemongrass or cinnamon essential oil. Due to the low percentage of essential oil in the plant, even only 0.03 to less than 1%, the amount of waste residue from the distillation process is quite large. According to the estimates of Thuy Moc Viet Company, 1 ton of lemongrass leaves can extract 3 kg of essential oil, and 1 ton of grapefruit peel can extract 4-5 kg of grapefruit essential oil. According to Hanoi Natural Essential Oils Joint Stock Company, for every 1 ton of lemongrass, it can extract about 2 to 3 liters of pure lemongrass essential oil. Regarding red lemongrass, it takes about 100-120 kg of raw materials to extract 1 liter of essential oil. Looking at the number of input materials, it is clear that the extraction of essential oils will generate a large amount of waste residue. This amount of waste is essentially organic compounds rich in carbon and multi-trace mineral elements, but there is no effective treatment solution. Many businesses do not consider the opportunity to take advantage of this waste source at all, so this amount of solid waste is often disposed of or burned directly, which continues to cause air and water pollution.

In the packaging and distributing process: Essential oils are usually packed into small dark glass bottles (brown, blue colors), with a capacity of only 5 - 10 or 15 ml, and a storage time (expiry date) is two years on average, so the number and volume of bottles to use is a large amount. On average, 1 hectare of lemongrass can extract 13 - 15 liters of essential oil, so it is possible to calculate that average of one ha of lemongrass requires 1,300 - 1,800 bottles/year. For example, in Tan Phu Dong district, Tien Giang province, there are about 1,600 hectares of lemongrass planting for essential oils production, we can calculate the number of bottles used annually from 2 to 3 million.

Essential oils as production materials can be stored in plastic containers/ cans with a capacity of 10 - 20 - 50 liters. Containers/ cans storing raw essential oils are usually made of organic polymers of chemical origin which are created during the process of extraction, distillation, refining and petrochemicals. Notably, essential oils stored in plastic containers usually have a short shelf life, only 3 to 6 months.

In addition, to deliver products to consumers, distributors and e-commerce platforms (for example: Shopee, Lazada or Amazon ...) use a lot of "extra" packaging made of paper, foam or plastic boxes which are not biodegradable, and they can persist in the environment for hundreds of years and decay into extremely toxic microplastics, causing water pollution, ocean pollution and adverse effects on human health and creatures.

In the process of circulation and distribution, the operation of transportation vehicles also consumes petroleum and generates large amounts of emissions, which are the main risks of air pollution, fine dust and greenhouse gasses.

Post-consumption disposal: The amount of glass bottles, plastic containers/ cans and other types of plastic paper packaging ... after use is quite huge. If not properly managed, it will be a source of extremely polluting solid waste. It is the fact that most of the after use glass bottles and packaging materials are usually thrown directly into the household trash along with other types of solid waste. Glass bottles which are used for store oil still have a concentrated amount of essential oil remaining. When they are thrown together with household waste, there is a potential risk of catching fire or causing burns, blistering of hands and mucous membranes if people accidentally touch them.

Thus, the production of natural essential oils according to the traditional linear model has been causing loss, wasting resources and putting negative impacts on the water, soil, air environment, and causing the problem of climate change as well. The transition from the traditional model of natural essential oil production to circular economy model is urgently needed to overcome all the challenges that businesses are facing in terms of economy as well as environmental and social responsibility towards sustainable development.

3.3. Opportunities for Circular Economy application in natural essential oil production in Vietnam

Based on the principles and contents of circular economy, lessons learnt from practical experience in the world, combined with consultation with economic and natural resources- environment managers, technical experts in essential oil production as well as experts on cleaner production, our research team proposed opportunities to apply circular economy in the natural essential oil industry according to the approach of the ReSOLVE framework, summary as shown in Table 1.

(1) Regenerate

It is applicable to use renewable energy sources in some activities such as in irrigation, drying of raw materials and distillation of essential oils or the operation of corporate offices. The source of biomass waste from processing and from popular agricultural by-products such as rice husks, sawdust, and solar energy (using solar panels) are the most available and accessible energy input sources from the perspective of natural essential oil producing enterprises.

Secondly, it is necessary to ensure the requirements of soil protection throughout the process of planting in material growing areas: do not use chemical fertilizers or chemical pesticides. Using chemicals can only improve yields in the first few years but not guarantee future sustainability because of the potential adverse impacts over time (degraded land, dead plants, and reduced yields). After the exploitation, it is necessary to preserve and spend time for restoring soil in the material growing area.

Using organic fertilizer (compost) made from the waste of the essential oil extraction process for the material growing area is a safe solution for the environment and helps enterprises to lower the cost buying chemical fertilizer.

Table 1. ReSOLVE framework on opportunities to apply circular economy in the production of natural essential oils

Approaches	Opportunities
	<ul style="list-style-type: none"> • Use renewable energy sources (biomass, solar energy...) in irrigation, drying of raw materials and distillation of essential oils • Organic and safety farming, pay attention to time for soil regeneration; use organic (compost) fertilizer from waste for material growing areas
	<ul style="list-style-type: none"> • Use agricultural by-products (containing oil) from other manufacturing industries for essential oil distillation • Supply used packaging and bottles to recycling companies in order to extend the life cycle of bottles to serve other manufacturing industries
	<ul style="list-style-type: none"> • Research, grow plants for high oil extraction efficiency, • Transform production technology towards optimizing input materials, energy and water • Optimize processes, reduce post-harvest material loss, • Optimize the transportation of raw materials and products, localize suppliers
	<ul style="list-style-type: none"> • Recall and recycle packaging • Recycle post-distillation residual for fertilizer and fuel (bio-pellets) • Reuse water, use post-distillation water to produce lotions and other products
	<ul style="list-style-type: none"> • Promote E-commerce • Promote online customer experience
	<ul style="list-style-type: none"> • Design packaging and bottles • Apply the Refill models • Use low-emission fridge in essential oil storage • Switch to high-efficient trucks, use lithium batteries instead of lead-acid batteries

Source: Compilation and recommendation by the research team

(2) Share

Share involves the activity to optimize resource use by sharing them among users and reusing them throughout the life cycle, extending the life of the product through maintenance, repair, or upgrading.

Natural essential oil producers can use agricultural by-products from other industries as a share of raw materials. For example: make use of by-products from the production processes of juice, dried fruit... which discharge a lot of fruit peels with high essential oil properties or after harvesting, pruning trees and young fruits... create excess by-products (branches, rotten roots, leaves, young fruits ...).

Second, manufacturers can recall used bottles and packaging and transfer them to glass recycling plants for alternative uses. By doing this, used bottles/ packaging have extended their life cycle in other production processes instead of being destroyed.

(3) Optimise

Optimization is about finding the solution with the cost - effective performance or highest operational efficiency according to the given constraints, by maximizing the desired elements and minimizing the undesirable elements. Optimization opportunities in natural essential oil production may include:

First, research to establish the regions for material growing or material procurement with better raw materials quality - that are plants with higher essential oil content, higher ability to extract essential oils than existing conventional plants.

Second, optimize the extraction/ distillation process of essential oils (heat, water, boiler...) to increase the efficiency of using input materials, water and energy, both saving energy and water costs and reducing waste.

Third, optimize the process of raw materials harvesting and transporting to the production (extraction) site to minimize the rate of loss and damage of input materials.

(4) Loop

Opportunities for material reuse and recycling are more evident in packaging recall and waste management.

It is necessary to establish packaging/ bottles collecting systems at dealers and product distribution places for reuse and recycle. In addition, it is needed to introduce policy to encourage consumers (for example, apply deposit - refund schemes), encourage dealers and distributors to aim for 100% of used product packaging/ bottles to be recycled and reused.

Waste residues from extraction/ distillation process should be recycled and reused, for example in the form of animal feed or organic (compost) fertilizer. Organic (compost)

fertilizers can be applied directly at the raw material growing area or supplied to the market. Waste residue also be processed to line livestock barns, used as a substrate for plant growth (typically as mushrooms) or as fuel pellets.

The water used for the extraction/ distillation process can be recovered to be used for the distillation of the same essential oil to take advantage of the heat as well as the essential oil properties left over from the previous distillation. This water source can also be used to wash raw materials or water the trees in the material growing areas.

The water obtained after distillation will be separated into essential oils and scented water. This liquid has gentle properties, should not be discarded but used to make products such as mouthwash, toner.

(5) Virtualise

Digital transformation in production and business aims at changing the way business models operate and bringing higher efficiency, and newer production values. The opportunity of using e-commerce platforms to bring products to consumers is increasing, both helping enterprises affirm their position in the market with trade recorded by the system while also helping to more easily control revenue and costs. Digital transformation also brings convenience in terms of conveying messages to consumers and to enterprises themselves. Digital transformation also helps reduce costs for businesses through easy management of inventory and monitoring of important production processes.

(6) Exchange

In order for packages and bottles containing essential oils to be recycled more easily after being collected, enterprises need to innovate the process of designing packages and bottles; switch to environmentally friendly packaging and bottles that are easy and multiple recycle and reuse.

Second, enterprises can use the type of refrigerators which eliminate greenhouse gas emissions and low ozone depletion in products store.

Third, in the process of transportation and distribution, it is necessary to switch from gasoline/ petrol trucks and forklifts to environmentally friendly electric energy vehicles and vehicles using lithium batteries instead of lead-acid batteries. Using such types of vehicles may help significantly reduce greenhouse gas emissions and harmful substances (lead, acid) discharged into the environment.

The diagram in Figure 3 clearly presents the flows of materials and goods in the direction of circular economy in the natural essential oil production: Blue arrows indicate goods that are in normal circulation; red is the waste/ residual flows; green is the material circulation flows.

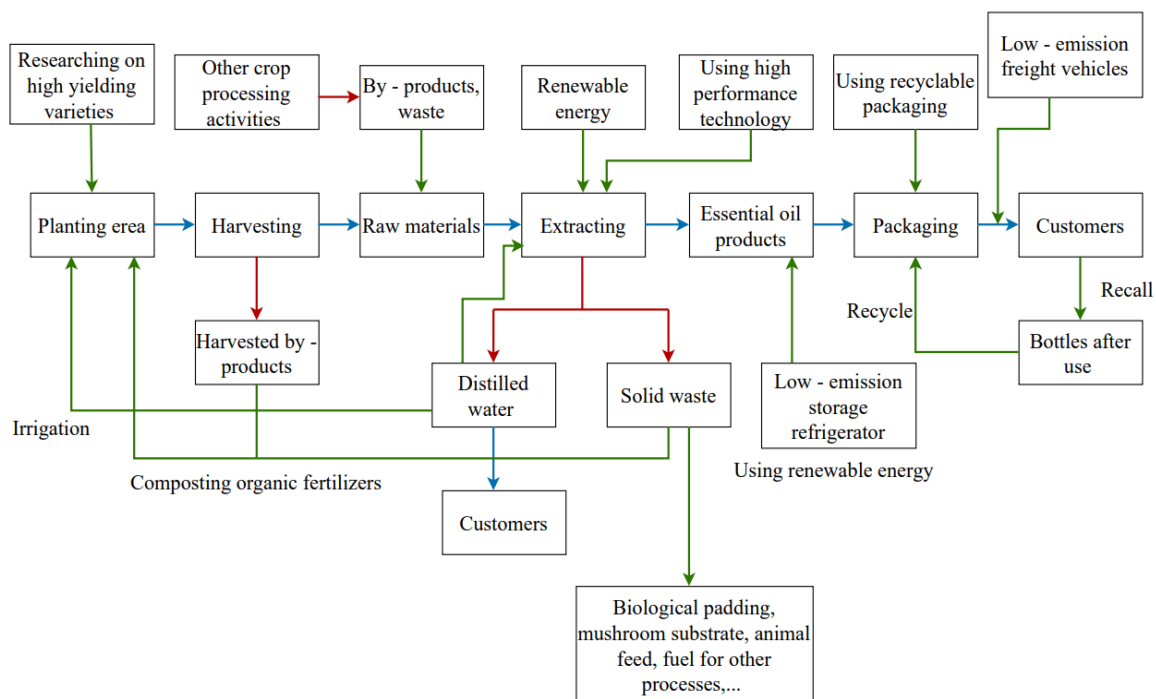

Figure 3. Proposed circular economy in the production of natural essential oils

Source: Compilation and recommendations by the research team

4. Conclusion and Recommendations

Natural essential oil production is an industry with a lot of potential in both the global and Vietnamese markets. In the general trend of global and Vietnam to transform from traditional linear economic models to circular economic models, aims at connecting economic processes, ensuring materials to be recovered, restored and regenerated, and keeping the materials in use as long as possible, Vietnamese essential oil producing enterprises should be aware of their responsibilities and seize this opportunity. The transition to the circular economy not only helps enterprises in sustainable business, extending the ability to penetrate the global market but also contributes to practicing corporate social and environmental responsibilities.

Enterprises producing natural essential oils in Vietnam should take the following things into account:

- Implementing the transformation to circular economy model in a proactive way, seeking out advanced technology and potential financial sources, carrying out product marketing, improve production and sales skills towards friendly products and efficient business;
- Be aware of the Extended Producer Responsibility (EPR) in the concern of the recall for recycling or treating of all types of packaging, bottles and jars; proactively innovating product and packaging design to make it easier, more convenient, and cost-effective to collect, simultaneously creating a more friendly image for customers;
- Based on the circular economy model to build a Circular Economy Business Model (CEBM) which is suitable to the conditions, circumstances, needs and corporate culture.

In order to orient and promote enterprises to apply the circular economy, the government needs to focus on a number of solutions as follows:

- Quickly complete and promulgate mechanisms and policies to promote the circular economy, complete the guiding policy framework and criteria for the circular economy for production and business sectors and fields; introduce incentive mechanisms related to corporate income tax, value added tax, soft loan and land incentives, increase incentives for businesses to use renewable energy;

- Promoting communication to raise awareness of businesses and stakeholders in the value chain of natural essential oil production as well as public awareness about the need, requirements, models and benefits of natural oil production circular economy; diversifying communication channels, reaping benefit of internet and 4.0 industry;

- Planning and publicizing the planning of raw material growing areas/ regions in order to contribute to strengthening linkages in the production value chain, facilitating enterprises to be proactive in production; localization of supply to reduce transportation distance in order to save costs, reduce fuel consumption, reduce the rate of material loss and damage;

- Promote the development of the recycling industry and the market for recycled products, specially emphasis on recyclable packaging and products in order to promote packaging collecting and recycling activities;

- Boost R&D of high-yield oil harvesting plant varieties as well as technical solutions in a circular economy model to reduce amount of waste/ residues in manufacturing process, reduce negative impacts to resources and the environment;

- Design, build and operate social infrastructure systems in accordance with the requirements of the circular economy;

- Implement effectively the roadmap of greening in the field of transportation, improve emission standards for vehicles, and convert means of transportation in the natural essential oil production industry - an industry of the “material-intensive”, which has a huge demand for transportation.

Abstract

The food and beverage (F&B) industry in most countries is under increasing pressure from consumers, nongovernmental organizations, governments, and other stakeholders to improve sustainable practices across their operations and supply chains. Applying the life-cycle assessment provided in the OpenLCA software package, this paper provides a showcase of greenhouse gas (GHGs) reduction within the sustainable food value chains of the Pizza 4Ps company. Our preliminary analysis of carbon footprint reveals that Pizza 4Ps' 1kg pizza emits 0.0411 kg of CO₂ eq into the atmosphere. Thanks to the use of organic materials in food processing activities, Pizza 4Ps is significantly more eco-friendly than the standard pizza value chain, which emits 2.08 kg of CO₂ eq.

Keywords: *carbon footprint, life-cycle assessment, sustainable food value chains*

1. Introduction

Food system activities are inextricably linked with climate and weather, environmental resources, and human behavior. GHG emissions from food systems are a major contributor to climate change. Globally, food system activities contribute 21-37 percent of total anthropogenic GHG emissions, compared with about 10 percent from food production alone and 18-29 percent from food production and land use change (Rosenzweig et al., 2020). Land use change, especially deforestation, forest degradation, and peatland conversion, contributes to substantial GHG emissions. Total GHG emissions from the food system were about 16 CO₂ eq per year in 2018, or one-third of the total global anthropogenic GHG emissions. Three-quarters of these emissions, 13 Gt CO₂ eq per year, were generated either during on-farm production or in pre- and post-production activities, such as manufacturing, transport, processing, and waste disposal (Rosenzweig et al., 2021). The remainder was generated through land use change of natural ecosystems to agricultural land. Substantial CH₄ emissions are best attributed to the specialized production of beef in large production systems. During 1990-2018, land use change emissions decreased while pre- and

post-production emissions increased (Tubiello et al., 2021). Post-production food system activities contribute to GHG emissions, albeit to a lesser extent compared with production-related and land-use activities. Post-production food system activities account for 18 percent of total GHG emissions from the global food system compared with 58 percent from food production and 24 percent from land use change (Poore and Nemecek, 2018).

Approximately 15 percent of food-related carbon emissions pass through restaurants (Kling and Hough, 2010). Food loss and waste exacerbate the climate change crisis with its significant GHG footprint. When food ends up in landfills, it generates CH₄. Food loss and waste account for between a quarter and a third of total global primary production (Guo et al., 2020; Gustavsson et al., 2011), and a 75 percent reduction is likely to result in a 10 percent decrease in GHG emissions (Springmann et al., 2018a). There are considerable differences between food types in terms of GHG emission levels measured in kilograms of carbon dioxide equivalents per kilogram (kg CO₂e). For example, vegetables such as zucchinis (0.25 kg CO₂e) yield approximately 50 times less GHG emissions than beef (12.29 kg CO₂e) (Reinhardt, 2016). As a part of ecologically sustainable practices, restaurants can help diners reduce their carbon footprint via dish choices. The utilization of local foodstuff and the decrease of animal protein in the menus can be a good strategy to encourage sustainable actions in food service meal production.

With its significant carbon footprint, the food and beverage (F&B) industry which is a major employer in most countries is under increasing pressure from consumers, nongovernmental organizations, governments, and other stakeholders to improve sustainable practices across their operations and supply chains. Sustainability is an approach to integrate social, economic, and ecological impacts within a robust business strategy. It is an enduring movement and increasingly impacts how business is undertaken and how consumers buy products.

In 2015, 196 countries, including Vietnam, adopted the Paris Agreement with the core objective of keeping the global average temperature rise to below 2°C above pre-industrial levels while pursuing efforts to keep it below 1.5°C for the survival and thriving of human beings and all creatures on the Earth. To be able to meet those climate targets, countries need to join hands and focus on GHG reduction across all sectors. Vietnam has released a new updated Nationally Determined Contribution under the Paris Agreement, in which the country increases its unconditional greenhouse gas (GHG) emissions reduction target to 15.8% by 2030 relative to a business-as-usual scenario from the reference year 2010 and including land use, land-use change, and forestry (LULUCF). Conditionally to international support and financing, through bilateral and multilateral cooperation, Vietnam has set an emissions reduction target of 43.5% by 2030. Under its previous NDC, released in 2020, Vietnam set GHG emissions reduction targets of 9% (unconditional) and 27% (conditional). In Vietnam, according to the updated NDC, the source of GHG emission from agriculture is identified to contribute around 20% of the total amount of GHG emission in 2020.

In response to recent government measures, an increasing number of F&B retail players and restaurants in Vietnam are adopting more sustainable and eco-conscious efforts. Several restaurants, hotels, and the F&B sectors have taken the opportunities to switch into

and become pioneers in sustainable development in the food production industry, such as Pizza 4P's, Laguna, Les vergers du Mekong, Sodexo, KOTO, etc. They have switched to a sustainable value chain with activities to reduce GHG emissions, reduce social and environmental impacts in each stage of the process of producing goods/ providing services, and change the consumer's behavior consumption. Changing our food systems to become sustainable and resilient is a powerful and smart way to realize progress toward achieving many SDGs. Shifting our diets can indeed unlock a multitude of environmental and health benefits and push us towards a virtuous uplifting spiral towards nourishing ourselves within planetary boundaries. Recently, citizens have paid more attention to their health and food consumption. Thus, by having a sustainable value chain, companies can add value to the final products or services, hence, realize some competitive advantages, such as cost reduction or product differentiation, and environmental contribution.

In recent decades, several environmental systems analysis tools have been introduced to estimate the environmental burdens related to agricultural production. The main methods adopted in scientific literature are the following: Product Environmental Footprint, Environmental Impact Assessment (EIA), Environmental Auditing (EA), System of Economic and Environmental Accounting (SEEA), Material Flow Analysis (MFA), and Life-cycle Assessment (LCA) (Boenzi et al., 2022).

Life-cycle Assessment (LCA) is an appropriate methodology to assess the environmental impact of a product/service or process by adopting a quantitative approach. It is based on Life Cycle Thinking, a paradigm that considers the environmental impact at all stages of the life cycle. Therefore, at the global level, LCA is considered one of the most reliable methodologies to assess the environmental impacts of products/services or processes and to identify effective solutions to address sustainability issues (Notarnicola et al., 2017). The LCA technique can be applied with defined boundaries by adopting two strategies. The first strategy considers a complete life cycle analysis, so called “cradle-to-grave”; on the contrary, in the second strategy, only a part of the life cycle is investigated; it is called “cradle-to-gate”, “gate-to-gate”, or “gate-to-grave” depending on the boundaries considered (Boenzi et al., 2022).

This paper is presenting preliminary results of a study measuring carbon footprint based on life-cycle assessment of sustainable food value chains in a case study of the Pizza 4P's. The findings on the case study can be a showcase of GHGs reduction within sustainable food value chains.

2. Method

2.1. Scope of Study

As mentioned, F&B companies are the subjects of this study. Accordingly, the Pizza 4P's company is chosen as a case study for a few reasons:

(i) It is considered as a typical pioneer in promoting sustainable food value chain in Vietnam (SustainableVN, 2021). 4P's has a strong reputation for their commitment to

sustainability, and their efforts have been recognized both nationally and internationally. This makes them an excellent example of a business that has successfully integrated sustainability into their operations, while also maintaining profitability

(ii) 4P’s have been actively working towards reducing their carbon footprint, sourcing local and organic ingredients, and implementing a circular economy approach in many phases of their value chain. Therefore, it is expected that there are a few good examples for other F&B companies to follow.

(iii) 4P’s is not just focused on its own business and profits, the company has gathered like-minded sustainable thinking companies in its value chain, supporting them to develop and encouraging them to adopt a sustainable and green approach. By doing so, 4P’s is contributing to a larger movement towards sustainability and promoting a culture of sustainability in the industry. This study also aims at recording the approach.

(iv) Finally, 4P’s has already published sustainability reports in 2020 and 2021, indicating that there is sufficient data available for our study. This enables us to analyze their sustainability efforts, understand their approach, and assess the impact of their sustainable practices.

2.2. Life-cycle assessment for measuring carbon footprint

In order to measure the carbon footprint (blueprint) of 4P’s, the LCA methodology is employed in this study. As discussed in the literature review, LCA is a widely accepted methodology for measuring the carbon footprint of products and services, especially in food and beverage industry. It provides a comprehensive and systematic approach to identify and quantify the environmental impacts associated with the entire life cycle of a product, from raw material extraction, manufacture, transportation, use, and end-of-life disposal (Figure 1).

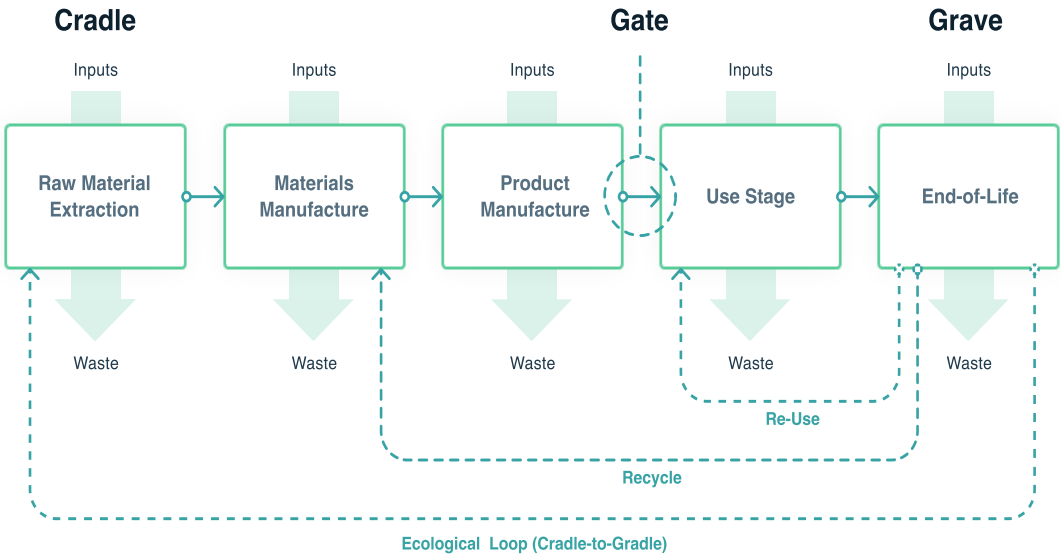

Figure 1. Boundaries of a LCA analysis

However, this study will focus on the Cradle to Gate instead of the entire Cradle to Grave to highlight the innovative approaches of 4P’s in the upstream of the value chain. This

will allow us to identify opportunities for reducing carbon emissions in the production and supply of raw materials, production processes, and transportation. By focusing on the Cradle to Gate, we can provide insights into the carbon footprint of 4P’s value chain and identify areas for improvement that can result in significant environmental benefits.

The use of LCA in measuring carbon footprint provides a comprehensive and systematic approach to identify and quantify the environmental impacts associated with the entire life cycle of a product. By focusing on the Cradle to Gate, we can identify areas for improvement that can result in significant environmental benefits, and the use of Open LCA provides a robust and flexible tool for conducting the analysis. Additionally, this study can support the development of a scope 3 inventory for 4P’s, further demonstrating the company's commitment to sustainability and environmental responsibility.

In addition, we employ Open LCA software to support our LCA calculation and analysis. Open LCA is an open-source software tool that allows for the creation and analysis of life cycle assessments. One of the key advantages of Open LCA is its flexibility in data entry and the ability to customize the analysis to suit specific requirements. Open LCA also provides access to a range of databases, including the ecoinvent database, which contains data on environmental impacts associated with various products and services. The use of Open LCA in this study allows for a comprehensive and robust assessment of the environmental impacts associated with 4P’s value chain, providing valuable insights for decision-making and sustainability performance improvement. Some sample results of the Open LCA are illustrated in Figure 2 below.

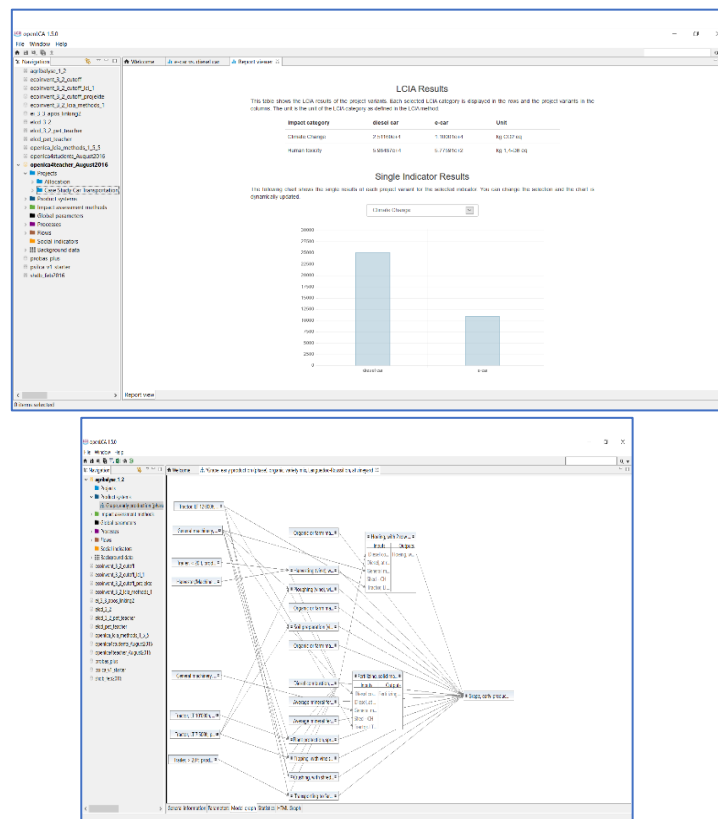

Figure 2. Example results of the Open LCA analysis on GHG emission

The result of our LCA analysis is also expected to support 4P's Scope 3. As scope 3 emissions refer to the indirect emissions that occur in the value chain upstream or downstream of the organization's activities (WRI and WBCSD, 2011). By conducting a comprehensive LCA analysis of 4P's value chain, we can identify the sources and magnitude of scope 3 emissions associated with the production and supply of raw materials, transportation, and other upstream activities. This information can be used to develop strategies for reducing scope 3 emissions and support the development of a scope 3 inventory for 4P's.

3. Preliminary results of the study

3.1. Value chain mapping for the 4P's company

This study will focus on the Cradle to Gate or the upstream of the 4P's' value chain, therefore the suppliers of the company is the focal point in this analysis. The suppliers included in this report are those have the remarkable practices relating to sustainability and GHG reductions.

• 4P's Cheese Factory

4P's Don Duong Cheese Factory, Lam Dong went into operation in 2011. A large amount of Vietnamese cheese is produced here and sold to hotels, restaurants and dairy shops throughout the region. Initially, the Don Duong cheese factory used less than 50 liters of milk per day. But now, with 30 workers, they use 4,000 liters a day to make 13 different types of cheese, from ricotta to bocconcini. All cheese produced here is 100% natural with no additives.

Circular economy

The liquid remaining after milk had been curdle and strained is whey. Whey is a byproduct of cheese making and has some commercial uses. It is an additive in many processed foods, including breads, crackers and in animal feed. In 4P's cheese factory, 20% of whey is used in the 4P's restaurants for making sauce, beer and pizza base. The other 80% is transported to Thien Sinh Farm which is a supplier of 4P's to grow grass, corn, and vegetables as well as to use as a drink for the cows.

Challenges and future actions

Water use and wastewater: The plant uses underground water and has its own water purification system. Water for cheese production is filtered by RO technology. Currently, due to the relatively small scale of the plant, there is no monitoring system for water used and wastewater. 4P's plans to build a new larger cheese factory in the near future in the same area. The water source will be tap water. With a larger area and operating capacity, the plant will have a monitoring system to measure the clean water used and wastewater for management information.

At the moment, the equipments are cleaned by hand after being used, which uses a large amount of water, and this water are not recoved. The new plant will have a separate section for cleaning the equipments, which would help save the water.

Solid waste: Milk cartons or the paper packages of heavy cream - an input for producing burrata - are usually made of aluminum and paper, which can be recycled into roofing sheets, flooring and pulp. After the milk cartons are put into the recycling line, the pulp will be separated and recycled into cartons. The rest is aluminum and plastic, which will be made into roofing sheets. The recycled product is 100% aluminum and plastic and has many advantages: Durability, no rust, heat and sound insulation, and environmental friendliness. They are suitable for houses in the coastal areas where there is high humidity. However, the milk cartons used in 4P's are put away and collected as other garbage by the local solid waste treatment company because 4P's cannot find a partner for recycling. This is an issue that needs to be solved with the new cheese plant.

• **Thien Sinh farm**

4P's uses the three indicators (including locally sourced, sustainably sourced, sustainably sourced with certification) to assess the sustainability of sourcing. From these points, it can be said that Thien Sinh farm is an important supplier in the value chain of 4P's as they adopt the organic farming techniques. 40% of the output in Thien Sinh is provided for 4P's.

Thien Sinh farm is located in Ka Don, Don Duong district, Lam Dong Province. Its products include vegetables like tomatoe, bean, kale, rocket, leek... and meat (pork and beef). The farmers in Thien Sinh started agricultural production 10 years ago. Before adopting organic farming, they planted corns in 4 years to recover and enrich the soil. Their total area is 14 hectares, in which 5 hectares are for vegetation. All the vegetables are grown in the greenhouse.

Reducing environmental footprint

As mentioned above, Thien Sinh farm use the whey, a by-product from the 4P's cheese factory, with agricultural techniques to turn it into a raw material for use. Whey is used as drinking water for cows, mixed with straw and grass for cows' food, and used to irrigate the soil. The farm's vegetables that do not meet the standards to be sold and a broken pizza dough from the kitchens of 4P's is also sent to Thien Sinh to be fed to the cows. Cow manure is composted to fertilize the soil. In addition to composting, the ingredients used at the farm are local, and the bacteria are also collected in the wild nearby. Thus, the farm produces almost no waste, but most of the waste is reused.

Thien Sinh's farming process is organic without the use of chemicals that can affect the environment and human health. The soil is improved by natural methods including resting the soil, intercropping, and using microbial fertilizers. One example of intercropping is that tomatoes and beans are planted on the land that will be used for producing rocket. The farm does not use pesticides. Pests are prevented by neem oil which is produced by the farm itself. Grass is cut by machine instead of using herbicides. As a result, the farm's agricultural products do not have residues of chemicals. At the same time, Thien Sinh does not discharge excess chemicals into the environment.

Challenges and future actions

Thien Sinh uses the spray irrigation method to water the plants. This method uses a sprinkler from below the water surface to the canopy through a system of pumps and pipes

with fixed nozzles. The spray system automatically rotates at an angle of 360 degrees, usually about 0.5-1m higher than the ground. The water used in Thien Sinh is pumped from the wells to a reservoir, then it runs to the piping system. A timer is set to water the farm several times a day, depending on the weather and temperature. In the dry season, the pump operates throughout the day while in the rainy season, it runs 12 hours a day. The water used have not been measured yet. Thus, it is recommended that a meter should be installed to estimate the water and drip irrigation should be used.

• **Zanya Coffee**

Zanya Coffee is a family cooperative in Lac Duong district, Lam Dong, under Langbiang mountain. Zanya coffee defines themselves as focusing on quality over quantity and developing personal relationships in Vietnam specialty coffee community. Langbiang mountain area provides the arabica coffee with unique aromas and flavours. Zanya would like to bring arabica specialty coffee from farm to cup to customers.

Benefits to the community

In Vietnam, a small but passionate group of customers of specialty coffee is slowly developing, especially in the big cities, thus the case that can also be observed in many other coffee-producing countries: when consumption increases in the country, the appreciation of the original product also increases. Producers learn to better assess the value and quality of their work and what Zanya Coffee has been doing opens to new techniques that keep one step of the value chain in the hands of the producers. This development is still in its infancy in Vietnam, but it has been initiated with the presence of companies like Zanya Coffee. In order to take control of the whole process of producing coffee as well as to encourage the farmers keep planting Arabica (rather than selling the land to real estate developers), Zanya Coffee buys the coffee cherries of surrounding family members and uses their own method to process. They rely heavily on multiple hand selections during the coffee processing, fermentation monitoring, drying on african raised beds and proper storage in Grainpro bags. Thus, they can pass on portions of the value the company generates to the community.

Challenges

Global climate change is increasingly leading to unpredictable weather conditions, making coffee plantation much more difficult in practice. Until well into the harvest season, the region was affected by heavy rainfall, making it much more difficult for a long time to reach the fields located on the mountain via the unpaved roads leading to them. Another issue is the price and quality. When coffee reaches a certain quality, it escapes the highly speculative environment of world market trade and becomes available to the specialty trade. It means that pricing primarily depends on quality. If coffee farmers commit to the effort required to grow high quality coffee, they will be rewarded with better price control and better income, which may be more sustainable than abandoning or selling the land.

• **Dalat Ecology**

Locating in Da Nhim commune, Lac Duong district, Dalat Ecology provide shiitake mushroom to 4P's. Five households including some K'Ho minority ethnic families participates

in shiitake production. They establish 10 mushroom houses, and the output of one mushroom house is 7-10 kilograms per day, which meets 20% - 30% of the demand of 4P's.

Shiitake mushrooms are a bit more picky about what they will eat when compared to oyster mushrooms, which will grow on coffee grounds, cardboard, or pretty much anything. Shiitake really need a wood-based growing medium to thrive and get the nutrients they need. Dalat Ecology uses the sawdust mixed with rice and corn bran as the beds for shiitake. One bed can provide mushrooms after 10 days after incubation and put into production again for seven to eight times (in 5-6 months) if it is mixed with good quality.

Circular economy

In mushroom production, water is an important input because mushroom prefer moist environments. Water is used to irrigate the roof to cool the mushroom house. A system of pipe is installed in every mushroom house to and spray water to keep the moist environment. Water is also necessary to soak the mushroom bed before planting. At Dalat Ecology, wastewater from soaking the mushroom beds is used to irrigate coffee plants. The mushroom bed, after reaching the end of its growth potential, still has a high nutritional content, so it is collected as compost to provide for coffee farmers.

Community development

Dalat Ecology was initiated by Mr. Quan after learning about sustainable development and environmentally friendly agriculture. He succeeded in convincing some K'Ho ethnic households in the area to participate in a project to produce shiitake mushrooms, which are a high-value agricultural product that does not affect the environment. Mushroom production requires a clean environment, so mushroom cultivation helps keep the soil, water and air environment free from dust and chemicals. As a result, the local ecosystem - where Bidoup Nui Ba National Park is located - is protected and people's health is ensured.

In this area, the main livelihood is growing coffee and vegetables. People do not want to make high-value specialty coffee because they usually receive money from traders first and then sell it back to those people during the harvest season at a relatively cheap price. Therefore, when compared to coffee farming, high-value shiitake production provides stable and higher income for ethnic minority households.

Future actions

The production model will be more effective if precise information is collected, including data on resources and fuel consumption. Currently, the main source of water used is groundwater and a small part is from the commune's reservoir. In the dry season, to cool the mushroom house, water is spray on the roof every half an hour for 10 minutes. In the rainy months (from July to October), it is unnecessary to cool the house. Electricity costs are about 1-2 million VND a month for one mushroom house. In the future, shiitake production households will need to install water meters to know the exact amount of water consumed for each production crop at different times of the year, thereby having a plan to save water and electricity and improve production efficiency.

• Orlar Vietnam Joint Stock Company

Orlar Vietnam Joint Stock Company is a company in the field of high-tech agriculture. Their goal is to meet the growing demand for fresh, safe and local products. The first technology is hydroponics. Plants are grown in pots with a substrate made from coir mixed with zeolite imported from Australia and added with microorganisms. The second is vertical gardening. This is a growing method that usually does not use soil or natural light. Plants are grown on posts or trays arranged vertically. The pots and trays are located in a greenhouse with a controlled environment. There are over 26 major products including lettuce, edible flowers, herbs, tomatoes, kale and strawberries. 4P's mainly uses edible flowers and strawberries from Orlar's farms.

Resource and energy efficiency

Orlar's technology does not use land, so it does not affect the natural soil. Plants are watered by drip irrigation technology. Drip irrigation involves placing tubing with emitters on the ground along side the plants. The emitters slowly drip water into the soil at the root zone. Because moisture levels are kept at an optimal range, plant productivity and quality improve. Drip irrigation also helps prevent disease by minimizing water contact with the leaves, stems, and fruit of plants. It allows the rows between plants to remain dry, improving access and reducing weed growth and reduces leaching of water and nutrients below the root zone. Time, money, and water are saved because the system is efficient. The number of labours needed decreased. In addition, the use of zeolite helps to retain water in the substrate, thereby saving more water than conventional hydroponic and normal drip irrigation. In terms of energy, since the water is used with the optimal amount, less electricity is needed to run the pump. Another advantage of the technology system is that the environment quality inside the substrate is ensured. The diseases can be controlled easily and there is no root disease. Once again, zeolite retains nutrients better, produces more nutritious products, and retains resources after harvest longer.

Saving the environment

Orlar uses systems designed to eliminate or significantly reduce the use of various inputs such as substrates, synthetic chemicals, and artificial light. The company uses no disposable input, captures 100% of nutrients, uses water nearly 100% efficiently, and uses 0.05% of the energy of other vertical farming operations. The technology helps control chemical residues and uses less land than traditional methods.

Challenges

Creating a controlled environment on a large scale will require more energy. For example, the company is experimenting with creating a stable low-temperature environment around the year for growing strawberries by installing a cooling system in vertical planting poles. Then the amount of energy consumed will increase, not only increasing costs for businesses but also making a relatively significant contribution to global GHG emissions.

Importing most of the important inputs including zeolite and fertilizer also increase the GHG emissions, which causes global climate change.

In addition, the application of high technology in agriculture, which brings high output and great value, also leads to the problem that local farmers who are lacking capital and knowledge may be excluded from the value chain of agricultural products. They will lose their livelihoods and have no opportunities to learn and improve their capacity to participate in this value chain.

- **Hasfarm Greens+**

Hasfarm Greens+, formerly known as The Fruit Republic, is a joint venture invested by Dalat Hasfarm in 2017. They have a separate farm and garden in Da Ron, Lam Dong. In 2021, the Hasfarm Greens+ brand is officially launched. Products supplied by Hasfarm Greens+ meet the food safety and quality standards with certifications issued by prestigious organizations in Vietnam and abroad, including FSSC 22000: 2018, GlobalGAP and VietGAP. Now they have 252 hectares in which 12 hectares are for vegetable production with the annual output of 9,000 tons. Hasfarm Greens provides 4P's with lettuces, bell peppers, tomatoes, etc.

Sustainable development has become one of Dalat Hasfarm's four distinguishing points, along with Innovation, High Technology, Sustainable Development, and Consumer Orientation. Many sustainable development solutions, such as organic waste recycling, energy-saving LED lighting systems, water treatment and reuse processes to save water resources in flower production, and Bio Pro technology, which uses beneficial insects, natural enemies, and biological fungi instead of chemical pesticides to protect human health and the environment, have been successfully implemented in the company.

Water saving

The company applies drip irrigation technology to save water and optimize water efficiency. In addition, irrigation water is also recovered through a system of pipes placed under the plant trays and pots, therefore it has a certain level of nutrients. It is estimated that the amount of water recovered and recirculated reaches 80% of the input water. The recovered water is used to irrigate the plants that are not too sensitive to nutrients in the water, for example ferns. In the future, the company will research to treat the reused water so that it is suitable for irrigating the vegetables.

Composting

The substrate is mainly coconut fiber, which is reused many times for different types of vegetables. After use, the substrate is collected and composted. Hasfarm Greens+ has a separate composting area. The company's composting process produces no odor pollution. As a result, the company can handle most of the waste from production.

Elimination of pesticides

Innovation can be seen as a winning tool for sustainable development. Doted with a professional laboratory, Dalat Hasfarm has started developing its own predator insects and micro-organisms since 2014. Using Bio-Pro helps reduce the presence of chemical residue on our different crops. safer for customers, protective for the workers and the environment. Their products include beneficial fungi, beneficial insects and potted soil.

The abuse of pesticides has directly eradicated natural enemies, causing insects and diseases to crop up, creating resistance and becoming stronger, so humans have to constantly invent new drugs to destroy them. Compared with the use of chemical pesticides to control pests quickly and effectively immediately, the use of natural enemies requires an initial time, because the impact time of natural enemies is longer. However, once the natural enemies have developed in sufficient numbers and suppressed harmful pests and insects, farmers almost do not have to use pesticides to prevent during the growing season.

Renewable energy development in the future

It is reported that utilizing clean solar energy will be a new milestone in Dalat Hasfarm's journey toward sustainable development. Dalat Hasfarm is taking a new step toward sustainable development by using clean energy from solar power - the BLT (Build - Lease - Transfer) model invested in by ecoligo Fund (Germany), developed and provided EPC contracting services by Vu Phong Energy Group. The project's kick-off ceremony was held on March 15, 2023. The parties' cooperation will not only aim for Goal 7 - Affordable and clean energy but will also contribute to the achievement of many other United Nations Sustainable Development Goals (SDGs), particularly Goal 8 - Decent work and economic growth and Goal 17 - Partnerships for the goals. The development of solar power should be expanded to Hasfarm Greens+ soon as the company also have a large area of greenhouse. Lam Dong has a high potential of wind and solar power with the total expected capacity is about 2250.06 MW.

Challenges

Similar to the case of Orlar, Hasfarm Greens+ have to import the seeds and fertilizers, which contributes to the GHG emissions. It is difficult for Hasfarm Greens+ to use the domestic seeds because the plants from domestic seeds are easily broken when growing and harvesting, resulting in high proportion of waste and increase in the cost. It is recommended that the company should invest in R&D to produce the seeds themselves.

• Yoshimoto Mushroom Vietnam Co., Ltd.

Yoshi mushroom is the main product of Yoshimoto Mushroom Vietnam Co., Ltd, which is located in Loc Son Industrial Park, Bao Loc City, Lam Dong province. The company adopts the Japanese-style organic and natural production process and the inputs are imported from the Netherlands. Healthy yoshi mushroom subject to Japanese standard is an important ingredient in the 4P's' menu.

Circular economy

Substrate from mushroom production has high nutritional content, which is preferred by the farmers. After 2-3 mushroom crops, the substrate is disinfected by heat and sold to local households and agricultural farms. The disadvantage is that the quantity is too large, leading to such high shipping cost that the local people can hardly pay.

Challenges

Yoshimoto's mushroom production process is based on technology and imported inputs. Each mushroom house needs relevant temperature and humidity level depending to each stage of mushroom growth, which consumes a lot of electricity. The imported mycelium from the Netherlands is stored in refrigerated containers at the temperature of -1°C. This is another significant energy consumption item that can contribute to greenhouse gas emissions. It is remarkable that all production materials are imported, from soil, nutrients to mycelium. The transportation of these materials leads to GHG emissions, which is a cause of climate change.

3.2. Measuring carbon footprint based on life-cycle assessment

Open LCA software was employed to calculate the environmental footprints of Pizza 4Ps. Table 1 below shows the environmental footprints of 1 kg pizza. Each selected indicator is displayed in the rows and the project variants in the columns.

Table 1: Environmental footprints of 1 kg pizza

#	Indicator	Pizza 4Ps (BAU)	Baseline	Unit
1	Climate change	4.11E-02	2.08E+00	kg CO2 eq
2	Climate change - biogenic	1.02E-03	5.97E-01	kg CO2 eq
3	Climate change - fossil	4.55E-02	1.41E+00	kg CO2 eq
4	Climate change - land use and transform.	-5.42E-03	7.34E-02	kg CO2 eq
5	Ecotoxicity freshwater	1.16E+00	2.20E+01	CTUe
6	Land use	6.93E+00	7.38E+02	Pt
7	Non-cancer human health effects	8.76E-07	8.84E-06	CTUh
8	Ozone depletion	4.02E-09	1.90E-07	kg CFC11 eq
9	Photochemical ozone formation, HH	2.02E-04	6.86E-03	kg NMVOC eq
10	Resource use, energy carriers	5.69E-01	2.52E+01	MJ
11	Resource use, mineral and metals	4.10E-07	4.95E-06	kg Sb eq
12	Respiratory inorganics	3.68E-09	1.88E-07	disease inc.
13	Water scarcity	9.75E-01	3.57E+00	m3 depriv.

As can be seen, the carbon footprint analysis reveals that Pizza 4Ps' 1kg pizza emits 0.0411 kg of CO2 eq directly into the atmosphere and has a total carbon footprint of 0.0822 kg of CO2 eq. This data clearly shows that Pizza 4Ps is significantly more eco-friendly than the standard pizza value chain (baseline), which emits 2.08 kg of CO2 eq directly and 4.8804 kg of CO2 eq in total.

Figure 3. Pizza 4Ps’ Carbon footprint vs the baseline

The following Figure 4 shows the relative indicator results of the respective project variants. For each indicator, the maximum result is set to 100% and the results of the other variants are displayed in relation to this result.

Figure 4. Pizza 4Ps’ environmental footprints vs the baseline

4. Conclusion

Food and beverage companies have a very significant environmental and social impact, and this has become a global issue. Food system activities, including producing food, transporting it, and storing wasted food in landfills, produce greenhouse gas (GHG) emissions that contribute to climate change, which account for 26% of global GHG, showing the huge impact that our diets have on climate change. Food systems cause the loss of 70% of biodiversity, restrict 3 billion people from a healthy diet, consume an enormous amount

of fresh water, equivalent to 304 million swimming pools, and one-third of our food goes to waste, etc. Food is also the largest consumption emission sector within cities, and it is foreseen that 80% of the world's food will be consumed by 2050. As the fact that, we depend on healthy ecosystems and healthy people to produce our food, yet at present, our food systems make us and our planet sick.

The food and beverage (F&B) industry in most countries is under increasing pressure from consumers, nongovernmental organisations, governments, and other stakeholders to improve sustainable practices across their operations and supply chains. The improvement is an enduring movement and increasingly impacts how business is undertaken and how consumers buy products. This paper provides a showcase of GHGs reduction within sustainable food value chains of the Pizza 4Ps company.

Acknowledgment: This paper is based on the research results obtained from a study about sustainable value chains under the “Urban Food System Working Group” program funded by the World Wildlife Fund in Sweden (WWF-Sweden) and partially implemented by WWF-Viet Nam. The findings, interpretations and conclusions presented in this paper do not necessarily reflect the views of both WWF-Sweden and WWF-Viet Nam.

COMMUNITY-BASED FOREST MANAGEMENT IN XUAN LIEN NATURE RESERVE

Nguyen Quang Hong
hongktqd@neu.edu.vn

Do Mai Linh
mailinh14062002@gmail.com

National Economics University, Hanoi, Vietnam

Abstract

This research article investigates community-based forest management through contractual arrangements in 12 villages/hamlets across five buffer zone communes in the Xuan Lien Nature Reserve, Thuong Xuan district, Thanh Hoa province. By utilizing methods such as data analysis, descriptive statistics, the article assesses the current situation and outcomes of forest management. It evaluates the factors influencing community-based forest management, identifies strengths, weaknesses, opportunities, and challenges, and proposes solutions to improve community-based forest management in the Xuan Lien Nature Reserve.

Keywords: *Forest management, community, Xuan Lien Nature Reserve*

1. Introduction

Mountainous regions cover two-thirds of Vietnam's territory and are home to over 24 million people belonging to 54 ethnic groups, particularly communities of ethnic minorities whose lives are intimately connected to land and forests. These areas are also the primary focus of forestry activities. Therefore, the socialization of the forestry sector is not only a practical requirement in Vietnam but also aligns with global development trends.

The Land Law of 2003 and 2013, the Forest Protection and Development Law of 2004, and the Forestry Law of 2017 have provided legal frameworks for forest management through land allocation and forest allocation to communities. Local communities are now considered genuine stakeholders with established rights to land and forest use, as well as entitlements, obligations, and benefit-sharing mechanisms from forests. In some areas, land and forest have been allocated to communities as stable, long-term management entities. Practical experiences have shown that community-based forest management is a feasible model economically and socially, suitable for the traditional production practices of many ethnic groups in Vietnam. However, communities have only been granted limited rights and control over the allocated areas.

Thanh Hoa province's Thuong Xuan district is a mountainous area located in the western part of the province. The region's diverse terrain consists mainly of hills and mountains, with a large forested area covering 80% of the natural land. These forests play a crucial role in environmental protection and improvement, serving as protective forests at the headwaters of the Chu River basin, regulating water resources during both dry and rainy

seasons. Due to the coexistence of multiple ethnic groups (Muong, Kinh, Thai, etc.) in Thuong Xuan district, forest management predominantly relies on local communities, particularly in the Xuan Lien Nature Reserve. This reserve is situated at the transition zone between the Northwest and North Central regions, boasting high biological diversity and a rich ecosystem composition. In recent years, the Xuan Lien Nature Reserve has implemented forest contractual arrangements with surrounding villages and communes.

However, practical implementation has revealed various existing issues in community-based forest management in the Xuan Lien Nature Reserve. Therefore, this study aims to investigate the current situation of community-based forest management in the Xuan Lien Nature Reserve, Thuong Xuan district, and propose effective solutions to contribute to community benefits.

2. Literature review

2.1. The formation process of community-based forest management

According to the report by Do Anh Tuan and colleagues, community-based forest management in Vietnam has been implemented since the 1980s. Initially, the form of community-based forest management was carried out by assigning forest management responsibilities to households. Later, this model was expanded and developed with two community-based forest management approaches applied in Vietnam, including forests assigned to communities for self-management and forests assigned to households, which can form associations to manage the forests.

2.2. Community-based forest management in areas near conservation and other areas

a. Similarities

- Focus on enhancing the role of local communities in natural resource management.
- Aim to ensure sustainability in forest resource exploitation and use.
- Require attentiveness and flexibility to ensure the effectiveness and sustainability of forest resource management.

b. Differences

- Community-based forest management in areas near conservation sites is usually stricter and more closely monitored than in other areas, as these areas are particularly sensitive and require sustainable forest resource protection. In contrast, forest management in other areas may be more flexible, depending on the specific needs and conditions of the community and forest resources.

- Areas near conservation sites often face more risks in forest management, such as violations of forestry and criminal laws, encroachment on conservation-planned areas, illegal logging, and the use of harmful chemicals. Therefore, close contracts need to be established between the parties to ensure the rights and obligations of each party in forest management. These contracts should ensure transparency, openness, adherence to deadlines, and strict enforcement. In contrast, in other areas, community-based forest management also requires transparency and openness but may not have strict legal regulations like in Nature Reserve.

- Areas near conservation sites have higher political and social influences due to their location and the level of government and international organization interest in forest conservation. Therefore, implementing community-based forest management in these areas may require closer collaboration with conservation support organizations and groups. In contrast, other areas may not face such political and social challenges.

2.3. Forests assigned to communities in nature reserve in Vietnam

a. Pu Hu Nature Reserve

Pu Hu Nature Reserve is located in Quan Hoa and Muong Lat districts, in the northwest of Thanh Hoa province, Vietnam, about 134km northwest of Thanh Hoa city.

In Pu Hu, community-based forest management is carried out through the establishment of groups and the formation of a forest management council, with members representing households and working together with the Management Board of Pu Hu Nature Reserve. These groups hold regular meetings to discuss forest management-related issues, make decisions, and propose appropriate solutions. Some activities carried out by the local communities in Pu Hu include forest monitoring, afforestation, timber harvesting, and selling forest products. However, all these activities are conducted under the supervision and guidance of the Pu Hu Nature Reserve Management Board to ensure that they do not harm the environment and ecology of the reserve.

The community-based forest management approach in Pu Hu has brought many benefits to both the local community and the environment. Through active participation in forest management, this model helps improve incomes for households while maintaining and protecting forest resources for future generations. However, to date, no community in the area has been granted a certificate of land use rights for forests. The Pu Hu Nature Reserve Management Board only provides forest protection contracts on an annual basis according to Government Decree No. 168/2016/ND-CP dated December 27, 2016.

b. Nam Kar Nature Reserve

Nam Kar Nature Reserve covers a total area of 24,555 hectares, with the core area located in Lak district, Dak Lak province, Vietnam. The reserve plays a significant role in protecting forest ecosystems, conserving endangered animal and plant species, and also serves as a watershed for the Mekong River.

The management board of Nam Kar Nature Reserve has collaborated with authorities at all levels and local communities to establish agreements and commitments to protect the forest. These agreements include not practicing slash-and-burn cultivation, hunting, trapping wild animals, and harvesting forest products that could negatively impact forest resources. Additionally, the activities of forest protection management stations throughout the region have achieved positive results. However, external support has been ineffective, and there is no common understanding of the purpose of forest resource conservation between Nam Kar Nature Reserve and local communities in the buffer zone. These communities still exert various adverse impacts on forest resources due to their unmet daily needs.

2.3. Lessons learned

Based on a comprehensive study of community-based forest management in several Nature Reserve in Vietnam, the following conclusions can be drawn:

- Community-based forest management has become one of the popular approaches worldwide and in Vietnam to manage forest land, contributing to the livelihood stability of ethnic minority communities who rely on forests.

- Village communities have established regulations for forest management and use. However, there is a need for more organized and equitable mechanisms for sharing the benefits derived from forests among community members.

- Forest management in many communities has shown clear environmental effectiveness, but economic effectiveness is still limited. Therefore, community-based forest management needs to balance economic feasibility, social equity, and environmental sustainability.

- Community-based forest management in Vietnam takes various organizational forms, including village-level, ethnic minority-based, and household group-based management. In practice, there is no single optimal form of management that applies universally but rather depends on specific community

3. Method

3.1. Data collection methods

a. Secondary data collection method

Relevant legal documents related to community-based forest management, as well as documents and materials related to land and forest allocation, leasing, and transfer to communities, were collected from the People's Committee of Thanh Hoa Province and various levels of state management agencies responsible for land and forest resources (such as the Department of Statistics, the Department of Natural Resources and Environment, and the People's Committees at the district and commune levels in Thanh Hoa Province).

b. Primary data collection method

Direct interviews were conducted with one leader and one forest management officer responsible for community-based forest management. Additionally, 60 households from five buffer zone communes participating in community-based forest management in the Xuan Lien Nature Reserve were interviewed.

These interviews provided information on the management process, policies, and methods of community-based forest management, as well as the challenges and limitations encountered during implementation. Furthermore, interviews with households in the buffer zone helped gain a deeper understanding of the motivations, needs, perspectives, and awareness of local communities regarding community-based forest management. Based on these findings, appropriate solutions can be proposed to enhance the effectiveness of community-based forest management and meet the communities' needs.

3.2. SWOT analysis method

The Strengths, Weaknesses, Opportunities, and Threats (SWOT) analysis framework was used to analyze community-based forest management in the Xuan Lien Nature Reserve, Thuong Xuan District, Thanh Hoa Province. The results of the analysis serve as an important basis for proposing solutions to strengthen community-based forest management in the Xuan Lien Nature Reserve.

3.3. Analysis and Synthesis method

Analyzing the results and evidence obtained during the study on community-based forest management in Xuan Lien Nature Reserve, Thuong Xuan District, Thanh Hoa Province, and then synthesizing them to propose more effective solutions for community-based forest management.

3.4. Descriptive Statistics and Data Analysis using SPSS Software

Summarizing, describing, quantifying, and analyzing data systematically and simply, evaluating important characteristics of the dataset quickly and efficiently.

4. Results and Discussion

4.1. Description of the Study Area

Thuong Xuan is a mountainous district located in the western part of Thanh Hoa province. It is situated 54 km west of Thanh Hoa city. Thuong Xuan shares borders with administrative units such as Bac Quang (Ha Giang province) to the north, Mai Son and Quan Hoa to the east, Thach Thanh and Bim Son to the south, Muong Lat and Tua Thanh (Dien Bien province) to the northwest, Song Ma and Ham Tan (Son La province) to the west. In terms of topography, the entire district gradually slopes from the northwest and west to the east and south. There are many mountain ranges, such as Chom Vin in Bat Mot commune, which reaches an elevation of 1,442 meters above sea level. The terrain is divided by rivers, including Khao River, Chu River, Dat River, and Dan River. There are numerous terraced hills and small-scale agricultural lands. The highland communes mainly consist of terraced rice fields that rely on passive irrigation and are prone to erosion. Thuong Xuan has a temperate climate, with cold winters and cool summers.

Xuan Lien Nature Reserve is located in the upper watershed of Chu River, within the administrative boundaries of five communes: Bat Mot, Yen Nhan, Luong Son, Van Xuan, and Thuong Xuan town, Thuong Xuan district (Thanh Hoa province). Xuan Lien Nature Reserve is evaluated as a biodiversity center representing the Northwest and North Central regions. The total area of Xuan Lien Nature Reserve is 27,668 hectares, including 19,800 hectares of strictly protected area, 7,848 hectares of ecological restoration area, and 20 hectares of service and administrative area. Xuan Lien Nature Reserve is renowned for its diverse and abundant forest flora and fauna, with characteristic evergreen tropical forests typical of northern Vietnam. The ethnic communities living around the Nature Reserve, mainly the Muong and Thai people, have preserved many unique cultural customs, lifestyles, and traditional practices. All the valuable natural and human resources provide a basis for the development of ecotourism and community-based ecotourism activities.

4.2. Forest Land Management Model in Xuan Lien Nature Reserve Changes Community Awareness of Forest Protection

Community participation in forest management and use has been established for a long time. With land and forest allocation policies and the implementation of various other policies, people's perception of the role of community-based forest management and land use has significantly changed. Survey data shows that the majority of residents believe that community-based forest management and land use play a significant role in protecting water resources (78.3%). Over 60% of respondents consider it very important for increasing income, but most people believe it is less important in terms of firewood and forest product exploitation.

Table 1. Community interview responses on benefits of participating in Community-Based Forest Management

Benefits of Participating in Community-Based Forest Management	Households (count)	Percentage (%)
Income generation	40	66,7
Water resource protection	47	78,3
Timber and firewood exploitation	3	5
Non-timber forest product exploitation	3	5

Source: Compiled by the author based on survey results

The research results indicate that community-based forest management and land use play a crucial role in water resource protection, ensuring water sources for production and livelihoods. Additionally, it contributes to income generation for community members. However, the revenue from firewood and timber exploitation in community forests is not significant and does not contribute much to household economies. Nevertheless, the benefits derived from community forests still hold importance for the local households.

4.3. Community-based forest management contributes to improving environmental quality Changes in forest quality

The allocation of land and forests to community management, along with community-based regulations, has significantly influenced forest quality. Since being handed over to community management, forest areas have witnessed thriving vegetation with dense canopies and vibrant undergrowth. This is an important factor in reducing the impact of rainfall on the forest floor, mitigating the flow rate, limiting soil erosion, and enhancing the forest's water retention capacity. These visible changes can be observed through naked-eye observations and are reflected in the results of interviews with local residents, as shown in Table 2.

Table 2. Community assessment of forest quality

Forest Quality	Households (count)	Percentage (%)
Improved	58	96,7
Unchanged	2	3,3
Declined	0	0
Total	60	100

Source: Compiled by the author based on survey results

The survey results indicate that the majority of respondents from the village communities (96.7%) believe that forest quality has improved, with no one perceiving a decline in forest quality. This demonstrates that the allocation of land and forests to community management has contributed to enhancing forest quality.

Soil erosion reduction

Soil erosion is a process influenced by various factors such as climate (rainfall, wind, floods), and sometimes human activities (deforestation for agriculture, infrastructure development, etc.) that impact the land surface, resulting in the loss or displacement of topsoil, humus, layers of weathered rock, and sediment along slopes. Through interviews with local residents, indirect assessments of soil erosion can be made (Table 3).

Table 3. Community responses on the degree of soil erosion

Degree of Soil Erosion	Households (count)	Percentage (%)
Reduced	47	78,3
Unchanged	7	11,7
Increased	6	10
Total	60	100

Source: Compiled by the author based on survey results

Through naked-eye observations made by local residents, it can be observed that soil erosion has significantly decreased, especially in areas previously affected. Now, instead of barren land, the landscape is covered by regenerated forests, grass carpets, shrubs, and a thicker layer of organic matter (darker-colored topsoil).

The survey data reveals that 78.3% of respondents believe that community forests contribute to reducing soil erosion. This is evident in the absence or minimal presence of erosion channels in cultivated land and undisturbed topsoil. Only 10% of respondents consider that erosion has increased, attributing it to soil washouts in flower fields and strong soil erosion during heavy rainfall.

Improvement in water quality

Water sources for production and domestic use in the buffer zone of the Xuan Lien Nature Reserve largely depend on natural sources, mainly rivers and streams. These water sources have been subject to declining water quality due to chemical use in agricultural practices by local communities. The use of chemicals, especially herbicides, in agriculture at the upstream areas has resulted in pollution. However, after the handover of forest tenure to the community, their increased responsibility for forest management and protection has led to greater concern for forest conditions and associated ecosystems, including water resources. This has led to the implementation of forest protection measures such as afforestation, reforestation, fire prevention, and more sustainable forest exploitation. These

actions help retain water within the forest and facilitate its supply to the community. Protected forests ensure the conservation and development of plant and animal species within them, which, in turn, helps maintain ecological balance and preserve water in both the soil and the forest. Consequently, it can improve the quality and the potential for the community to reuse water for production and daily activities.

Survey results show that over 80% of the population believes that the water source for production and daily activities has shown improvement compared to before. A small portion, less than 20% of the respondents, reported no change in the water quality, and there were no evaluations indicating a decline in water quality. This indicates that community-based management practices have indeed brought significant effectiveness in improving water quality for the local population. It is essential to continue and enhance these management efforts to ensure a sustainable water supply for the community's production and daily needs.

Table 4. Community responses on water quality

Water Quality	Water for production		Water for daily activities	
	Households (count)	Percentage (%)	Households (count)	Percentage (%)
Improved	50	83,3	51	85
Unchanged	10	16,7	9	15
Declined	0	0	0	0
Total	60	100	60	100

Source: Compiled by the author based on survey results

4.4. Factors influencing Community-based Forest Management at Xuan Lien Nature Reserve

Theoretical studies and direct surveys and interviews with two relevant local officials involved in community-based forest land management in Xuan Lien Nature Reserve revealed that factors related to legal regulations have a significant impact on the management and utilization of community-based forest land. These factors include regulations on forest land management, regulations on land and forest allocation to the community, regulations on benefits and financial support, rights and obligations of the community, and regulations and rules for community-based forest management.

The officials also highlighted the importance of natural and infrastructure conditions related to the allocated forest land. These factors, such as the scale of forest land area, distance from the community's residence to the allocated forest land, infrastructure, and particularly the quality and availability of forest resources, have a significant influence. Economic factors, such as household economic conditions, market for forest products, borrowing and utilization of loans by communities, are also of interest.

Table 5. Factors influencing Community-based Forest Management at Xuan Lien Nature Reserve

No	Code	Factors
Group 1		Legal Regulations (LR)
1	PL01	Enactment of legal documents
2	PL02	Implementation of legal documents
3	PL03	LR on land and forest allocation to the community
4	PL04	LR on types of forest land allocated to the community
5	PL05	LR on benefit issues
6	PL06	LR on support policies
7	PL07	LR on law violations
8	PL08	Conventions and agreements of villages/communities
Group 2		Natural and Infrastructure Factors
9	TN01	Scale of forest land area allocated to communities
10	TN02	Distance from the community's residence to the allocated forest land
11	TN03	Topography of allocated forest land
12	TN04	Social infrastructure (service system, market)
13	TN05	Technical infrastructure (transportation, irrigation)
14	TN06	Availability of forest resources
Group 3		Economic Factors
15	KT01	Dependence on forests by local residents
16	KT02	Market for forest products
17	KT03	Borrowing from banks and credit institutions
18	KT04	Utilization of community forest management funds
19	KT05	Sources of community forest management funds
Group 4		Social Factors
20	XH01	Indigenous knowledge of the community
21	XH02	Customs, traditions, beliefs
22	XH03	Role of forest rangers, agricultural officers
23	XH04	Role of other organizations (Farmers' Association, Women's Union, Youth Union)

Source: Compiled by the author based on survey results

One of the factors that receives special attention directly related to the communities is their indigenous knowledge, customs, traditions, and beliefs, as well as the role of other organizations in the community. These factors have a significant influence on community-based forest land management. Other factors, such as the level of education and age of laborers, receive less attention, which is consistent with previous studies. Since this is a form

of community-based forest land management, these factors have less impact compared to other management approaches.

Exploratory Factor Analysis (EFA) Results

Specifically, the research team used Principal Components Analysis with Varimax rotation to analyze 4 independent factors comprising 23 observed variables. The first EFA analysis resulted in all observed variables being suitable and grouped into 4 factor groups: PL, TN, KT, and XH.

Table 6. Related Component Matrix

	Component			
	1	2	3	4
TN03	.848			
TN02	.840			
TN04	.820			
TN05	.723			
TN01	.674			
PL08	.625			
PL06	.549			
PL05	.525			
KT03	.525			
PL02		.870		
PL03		.862		
PL01		.805		
PL04		.737		
XH03		.722		
KT04			.767	
KT05			.759	
XH01			.740	
XH02			.739	
XH04			.693	
TN06			.601	
PL07				.784
KT02	.503			.686
KT01				.684

The results indicate that the Bartlett's test yielded a P-value (sig. = 0.000) < 0.05, indicating that the observed variables in the factor analysis are statistically significant. The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy is 0.880, satisfying the condition (within the range of 0.5-1), indicating the suitability of factor analysis. The Total

Variance Explained is 80.171%, which is greater than the required threshold of 50%, indicating that the four factors explain 80.171% of the data variation. The Eigenvalues of all factors are greater than 1, meeting the requirement.

4.5. SWOT Analysis in Forest Management Based on Community Participation in Xuan Lien Nature Reserve

In order to achieve sustainable forest management and conservation in Xuan Lien Nature Reserve, involving the local community in the forest management and protection process is an effective approach. SWOT analysis is an important tool for evaluating internal and external factors in Xuan Lien Nature Reserve, helping managers develop appropriate strategies to enhance strengths, address weaknesses, seize opportunities, and cope with challenges.

Below is the SWOT analysis of forest management based on community participation in Xuan Lien Nature Reserve.

Table 7. SWOT Analysis of Forest Land Management Based on Community Participation in Xuan Lien Nature Reserve

<p>Strengths (S)</p> <ul style="list-style-type: none"> • Favorable land and climate conditions for forest land utilization. • Potential for community-based forest management and utilization. • Potential land resources for community-based management and utilization. • Communities with longstanding traditions of land management and utilization. • Forest land management and utilization based on community participation have contributed to improving income, especially for the poor, and have changed people's perception of the forest's role. 	<p>Weaknesses (W)</p> <ul style="list-style-type: none"> • Policies and laws related to forest land management and utilization lack specific regulations for the community. • Limited issuance of land use certificates for forest land, restricting community land use rights. • Low income from the forest, accounting for a small proportion of household income, leading to a lack of motivation and attention. • Market for forest products is unstable.
<p>Opportunities (O)</p> <ul style="list-style-type: none"> • Formation of linkages in the process of forest land management and utilization (co-management; linkages in the consumption of goods and services). • Community-based forest land management and utilization is receiving more attention as it has proven effective in many localities. 	<p>Threats (T)</p> <ul style="list-style-type: none"> • Difficulty in expanding forest land areas assigned to communities. • Future revenue from forest land is difficult to increase due to the increasingly scarce forest resources. • Expanding the market for product consumption is challenging.

Source: Compiled by the author based on survey results.

5. Conclusion

Community-based forest management in Xuan Lien Nature Reserve is a long-standing land use method influenced by natural and socio-economic conditions in the communities residing in and participating in forest land management. Community-based forest management has been implemented in Xuan Lien Nature Reserve for a long time, with various communities involved, mainly the Thai and Kinh ethnic communities living in Thuong Xuan province.

In Xuan Lien Nature Reserve, forest land allocation has been carried out for 12 villages in five buffer zone communes, covering an area of 14,285 hectares (51.63% of the total forest area in the reserve). All communities participating in forest land management have established forest land management regulations, and local authorities annually disseminate information to the residents in these communities. The benefits derived from community forest land, mainly non-timber forest products, are distributed according to these regulations.

Community-based forest management in Xuan Lien Nature Reserve contributes to increasing the income of local residents and stabilizing their livelihoods. Although the average income from forest land is not high for households, it is still a significant source of income for those who heavily rely on the forest. The main reasons for the relatively low income include the decreasing direct forest resources, inadequate land management and utilization mechanisms, and limited development of alternative forest resources such as tourism and related services. However, community-based forest management has helped change the perception of local residents regarding forest land management.

In the process of community-based forest management in Xuan Lien Nature Reserve, there are favorable conditions such as climate, land availability, community traditions, local knowledge, and cultural practices. However, there are also limitations and challenges, including inappropriate policies and laws specifically targeting the community, as well as limited rights of the community. Additionally, there are challenges in addressing regulatory changes, revenue generation from community forests, and product market consumption. On the other hand, there are opportunities for community-based forest management, such as the attention from the Party, the State, political and social organizations, and the community, the awareness of the residents in the community, the linkages between communities, and market opportunities. These strengths, opportunities need to be leveraged and limitations, challenges need to be addressed for further development.

To enhance the effectiveness of community-based forest management, several integrated solutions should be implemented, including increasing income from community-based forest management, enhancing activities that change the economic conditions of the participating communities, improving policies and laws related to community-based forest management, utilizing local knowledge, and further strengthening the role of local authorities and other organizations within the community.

Abstract

Carbon pricing has now been implemented as a key policy instrument for climate change mitigation in many countries globally. Through a literature review, we identify and assess the impact of factors influencing the design and implementation of a carbon pricing policy. Factors include the actual institutional system, business influence, public opposition, external factors and policy dissemination. From this, we see that obstacles to implementation need to be overcome by adapting the design of systems to meet different social interests. Preferential treatment and tax exemptions are thus common, which makes the incentives for emission mitigation less coherent across sectors. The results are of practical relevance for policy makers when designing and implementing carbon policies and indicate that carbon pricing needs to be part of a policy package in order to secure both rapid mitigation and a long-term decarbonisation. At the same time, carbon pricing for the steel industry has also been considered, the transition to green technologies is essential.

Keywords: *carbon pricing, climate change, policy instrument, steel industry.*

1. Introduction

The Paris Agreement (2015) on Climate Change sets an international goal to keep the average global surface temperature increase (compared to the end of the 19th century) below 2°C. Temperature stability requires that long-lived greenhouse gas emissions be net zero (UNFCCC, 2015). The IPCC report (2018) clarified that non-existence around or before 2050 is needed to limit the average temperature increase to 1.5°C and around 2070 to 2°C. The report makes a strong argument that temperatures above 1.5°C should be considered dangerous.

There is a growing consensus that carbon pricing - measured by the carbon content of fossil fuels or their emissions - is the most effective mitigation tool. Following the trend of liberalization and prioritization of market solutions, carbon pricing is becoming

increasingly important worldwide. Such carbon pricing is accomplished through the taxation or trading of GHG emission allowances in an emissions trading system. The emission trading system is often referred to as a “cap and trade” or a “carbon market”. The system also includes a voluntary carbon market and a carbon credit trading system (under the “carbon credits exchange mechanism”). The mechanism for exchanging and clearing carbon credits is the mechanism for registering and implementing programs and projects to reduce greenhouse gas emissions and generate carbon credits according to internationally recognized methods. internationally or nationally recognized, e.g. Clean Development Mechanism (CDM) under the Kyoto Protocol (Paterson et al., 2014). Carbon credits from programs and projects are exchanged on the carbon market or offset GHG emissions in excess of the allocated quota.

There have been a number of books examining the effectiveness of carbon pricing policies. Rabe has an excellent analysis of how politics is far from economic theory, regarding the pricing of carbon in “Can We Price Carbon”. He observes that policy adoption is just the beginning: “carbon pricing policies are not necessarily self-actualizing and evolving” (Rabe, 2018). Without concrete recognition, these efforts can be difficult to achieve. Wettestad and Gulbrandsen (2018) surveyed carbon markets in a range of specific jurisdictions from the EU to Tokyo to Kazakhstan.

The widespread and growing use of carbon pricing reflects confidence in its effectiveness. According to the World Bank's "Status and Trends in Carbon Pricing 2022" report (2022), as of April 2022, 68 carbon pricing instruments are in operation globally with Three other instruments are planned for implementation, including 37 carbon taxes and 34 ETS, covering about 23% of global greenhouse gas emissions. Also, according to this report, in just one year (from May 2021 to May 2022), a tax on carbon -bon was formed in Uruguay and three new ETSs went live in Oregon, New Brunswick and Ontario. Besides, carbon pricing tools are also planned to be implemented in Indonesia, Austria and Washington state (USA). Several other countries and regions such as Israel, Malaysia, and Botswana have announced their intention to develop carbon pricing while Vietnam has outlined a roadmap to establish an ETS. Several other jurisdictions in Africa, Central Europe and Asia are also in the process of continuing to assess the potential for implementing carbon pricing.

In 2005, the European Union launched the Emissions Trading System (ETS) as part of its climate action plan, which was the first international carbon market and one of a kind largest international carbon markets in the world. Several new factors need to be taken into account in the number of EU-wide subsidies phase 4 (2021-2030) of the EU ETS to be issued from 2021. Phase 4 allowances will be auctioned from 2021. Under the new regulations for phase 4, allowances are issued from January 2021 onwards (both auction and free distribution). Unlike during the transition between phase 2 (2008-2012) and phase 3 (2013-2020) of the EU ETS, the phase 3 allowance already on the market will not be replaced by the phase 3 allowance. 4 which will continue to exist in parallel. In the EU, some member states expressed dissatisfaction or requested a halt to the EU ETS extension and reform plans due to concerns about the impact of this policy on the low-energy country. In the short term,

high prices may lead to reduced energy use but will not provide investors in low-carbon projects with long-term certainty that carbon prices are stable.

According to the roadmap, Vietnam will pilot a carbon exchange in 2025 and officially operate it in 2028, so it is urgent to design a carbon market suitable for the current climate, regime and political situation of Vietnam. As committed at COP26, in order to achieve the goal of net-zero emissions by 2050, Vietnam faces the challenge of developing towards a low-carbon economy with outstanding growth rates, and will need to mobilize all resources, apply creative solutions. Currently, Vietnam has indirectly taxed carbon through the Environmental Protection Tax for fossil fuel producers and importers. However, this tax rate does not really reflect the nature of carbon pricing.

A well-designed carbon pricing mechanism can spur innovation and investment in low-carbon technologies that provide a competitive advantage. However, there are also notable challenges to achieving proper design. The first is carbon leakage - the phenomenon in which carbon-intensive industries or companies move operations to lower-cost jurisdictions. The second is overlapping or inconsistent policies. Policy makers must work carefully and thoughtfully to avoid potential overlaps and interactions between policy instruments, which can reduce effectiveness of the carbon pricing mechanism. The third is inefficient use of revenue. Carbon pricing tools can raise revenues significantly, but the effectiveness of many carbon pricing initiatives depends on how these revenues are spent. Revenues can be recycled to reduce other common taxes, protect lower income households, support cleaner technology, address equity and competitiveness concerns, or divert public funds to other public policy goals.

This led us to develop our main hypothesis: different sets of variables are playing a role in determining the adoption of carbon pricing in Vietnam. This study can provide a more comprehensive and in-depth look at the current and future application of carbon pricing to Vietnam.

2. Method

Our research focuses on the scientific literature related to the practical experience of carbon pricing policy, in particular the application, implementation and design of real carbon pricing policy tools. economy in countries. We use search terms including carbon tax, energy tax, environmental tax, emissions trading and carbon pricing in conjunction with implementation, adoption, and trade-off terms. We then proceed to the next round of review, where we read the reference lists of the selected articles to find additional articles that may be of interest and have not yet appeared in a more formal search ours. The articles were checked in the same way as previous articles and selected or eliminated. This resulted in a final list of articles that were relevant to our research questions and thus formed the basis for the qualitative review. The study should be seen as a literature review and review in which we have found a large body of research on this topic with enough content to draw relevant conclusions in our area of research. rescue.

Each study was analyzed based on three major questions: (i) According to the study, what are the main factors influencing the design and implementation of a carbon pricing

policy?; (ii) What are the specific aspects of the policy instrument (e.g. scope, rigor, immunity); (iii) why were these aspects chosen? After analyzing each of the pre-selected studies, the results were compiled by summarizing key implementation and application factors, as well as highlighting key design aspects found in the literature.

3. Results

3.1. Factors affecting the application of carbon pricing policy

Selected articles cover two main types of carbon pricing instruments, carbon taxes and emissions trading. The majority of countries are covered in the study when compared to an overview of existing systems provided by the World Bank (2022). Most of the policy instruments studied were in individual countries, with the exception of the EU ETS which is a regional policy and a few local policy instruments in the United States and Canada.

3.1.1. Political system and institutional factors

Carbon pricing, including carbon taxes and emissions trading, has been adopted by different types of governments around the world. According to some studies, some political systems are more favorable in introducing economic policy tools than others. Typically in the study of Harrison (2010), Andersen (2019) and Criqui et al. (2019) find that Proportional electoral systems tend to facilitate the application of a carbon tax, while international institutions have a mixed effect, in some cases promoting harmonization and in other cases weakening resolve to tax unilaterally, the study also finds that small or green double when close an important role in closing policy proposals. However, in contrast to the above conclusions, Skovgaard et al. (2019), Levi et al. (2020) argue that the composition of government in countries where carbon pricing systems exist today reflects the entire political spectrum, including left and right government, presidential and parliamentary democracy, as well as dictatorships. Through the research of Skovgaard (2019), a number of key observations have been synthesized: Carbon pricing has become a major global policy tool; Economic and financial crises create opportunities to promote carbon pricing; The international climate regime can support the adoption of carbon pricing through mitigation commitments and international financial and technical support; Inter-governmental learning in the same region is a useful tool to promote carbon pricing; Carbon-intensive economies tend to prefer emissions trading over carbon taxes.

3.1.2. Business influence

The influence of business and industry is emphasized in practically all studies. It has contributed to policy impediment (e.g. France, USA,...) and design influence to the extent that it reduces costs for industry and other businesses. Today, the remaining exemptions are sectors participating in the EU ETS. The Swedish experience shows that emissions reductions can be combined with economic growth. In addition to the above, another important advantage of taxation (compared to cap and trade schemes) is that it works well in conjunction with other tools of climate and energy policy, such as green certificates. , subsidies for renewable energy and regulations were introduced after (or in some cases before) the tax.

According to Haites (2018) review of business exemptions that occurred in all cases of carbon pricing, Speck (2013), Speck and Jilkova (2009) also noted that in this context In Europe, political constraints have made tax exemptions for manufacturing industries necessary as a prerequisite for implementation. According to studies such as Vehmas (1999), Harrison (2010), Andersen (2019), Criqui et al. (2019), business influence is also recorded in all Nordic countries, which claim to have the most ambitious carbon tax. Here, energy-intensive industries in particular were exempted, which can be explained by the neo-cooperative nature of these countries (Andersen, 2019) and the tight policy web between industry and government.

According to Oh et al. (2017), in Korea, strong market stabilization measures have been introduced with a focus on maintaining subsidy prices below a certain level, which should address some concerns of industries. In addition, free allocations have been used as a measure to compensate for potential damages caused by the emissions trading mechanism.

3.1.3. Public outcry

Numerous studies have shown that public opposition to increased costs and negative allocation effects are significant obstacles to the introduction of carbon pricing policies. In a study of 262 jurisdictions with carbon pricing, Levi et al. (2020) found that public perception of climate change is a strong driver of carbon pricing becoming higher.

Public outcry seems to have prevented the carbon policies being implemented in Australia, Canada and France as mentioned in the studies of Copland (2020), Harrison (2010), Criqui et al. (2019), Deroubaix and Leveque (2006). However, public outcry is not the only or even primary cause of policy abandonment, but often corporate opposition or political struggles play a more important role. Contrary to the experiences presented above, studies from typical Nordic countries by Kasa (2007), Harrison (2010), Criqui et al. (2019) show that public opposition should not be a major concern in the application of a carbon tax. Instead, people's awareness of environmental issues has prompted politicians to come up with policies.

In reviewing previous survey studies, Haring et al. (2018) note that public support for a carbon tax can be influenced by individuals and by the perceived consequences of introducing a particular policy instrument. Maestre-Andrés et al. (2019) make similar observations, namely that perceived fairness of carbon pricing is significantly associated with public acceptability.

Five common reasons leading to differences in attitudes and perceptions among individuals, causing public opposition to a carbon tax are often highlighted in the document, specifically as follows: First, the personal cost of taxes is thought to be too high; Second, the carbon tax can be regressive; Third, a carbon tax can be damaging to the economy as a whole; Fourth, a carbon tax is not expected to discourage high-carbon behavior; Fifth, governments may want to tax carbon to increase their revenues.

3.1.4. Outside influence

Although relevant to events or factors outside the field of climate policy, this could still influence the design or adoption of a carbon pricing instrument. In many countries, heavy reliance on fossil fuels also has a negative impact on carbon pricing policies.

Figure 1. EU ETS spot carbon price for 15 months

Source: refinitiv.com

The war between Russia and Ukraine has led European leaders to declare energy security and Russian fossil fuel independence a top priority. According to EU ETS transaction data from Refinitiv, While the cost of energy commodities - gas, electricity, coal - spiked due to the invasion. With such rising carbon prices, the EU ETS promotes significant public revenues to shift towards financing the green transition and can help break dependence on Russian gas.

In research related to the Covid-19 pandemic, Steffen et al. (2020) note that policies to adapt to shocks and crises should be introduced through designs and mechanisms that help mitigate risks. Steffen et al. argue that due to highly transparent price signals and political economy issues, carbon pricing policies are also more reactive than other policies.

3.1.5. Policy dissemination

There are many notable types of linkages in the form of sharing experiences and lessons and building capacity. For example, Biedenkopf et al. (2017) found that the EU, Norway and California all support China in various aspects of subnational ETS pilot projects and in developing a national system, processes appear to be driven by a clear need from the jurisdiction to design ETS.

For each ETS studied, the authors needed to consider the key external reference points that played a role in their development. An even greater challenge to achieve homogeneity of emissions trading policies across jurisdictions is the fact that international processes substantively interact with political and economic systems. domestic economy in the receiving jurisdictions.

Local political concerns are important mediators in the diffusion process. Similarly, understanding the ways in which NGOs facilitate or inhibit the establishment and operation of domestic ETSs is a recent but important area of research. Several international factors may also be important for carbon pricing. Skovgaard et al. (2019) used a clustering approach and found that political globalization, including participation in climate commitments, is an important driver of the adoption of the definition of carbon price (instead of range).

3.1.6. Strategies to support adoption and implementation

(i) Take it step by step and build alliances: Step-by-step implementation is an execution strategy where the idea is that the policy is initially launched with a fairly modest price of carbon and/or coverage and then increased in a stepwise manner as the policy progresses. widely accepted.

(ii) Design modification: Modifications to the design of the carbon pricing system take place regularly to overcome objections from households as well as the business sector.

(iii) Pricing carbon as part of the policy mix: Systematic evidence regarding the implementation of carbon pricing - a carbon tax and a greenhouse gas (GHG) emissions trading system (ETS) - is sparse. Implementation of existing carbon taxes and greenhouse gas ETS can help policymakers make informed choices about whether to introduce these tools and improve their design.

3.2. Carbon pricing: the case of the steel industry

The global climate goals have highlighted the need for a system-wide approach to decarbonisation, one that includes targeted national policy and industry-specific change. In this context, synthesizing from other studies, we examine the policy and price barriers to the decarbonization of the steel industry, taking the UK as a prime example.

Steel production is a carbon and energy intensive process. Globally, for every ton of steel produced an average of 1.85 tons of CO₂ is emitted. In 2019, the UK steel industry emitted around 12 million tonnes of CO_{2e} (including indirect emissions from electricity generation), accounting for 11.5% of UK industrial emissions and 2.7% of the UK's total greenhouse gas emissions in 2019. Steel production therefore has an important role to play in meeting the UK's Net-zero target and any future carbon pricing scheme will have a significant impact on the industry.

Figure 2. Greenhouse gas emissions from the most promising options for green steel production compared to the carbon intensity of the grid

Source: Data from BEIS annual report and accounts 2019 to 2020

The decarbonization industry is a key focus of the UK's approach to net zero (Busch et al., 2018). A number of national policy measures are contributing to this goal: For example, the UK government's "Ten Point Plan for a Green Industrial Revolution" sets out the government's approach to 'building a better' while bringing the country closer to industrial decarbonisation through a focus on green energy development amid domestic covid recovery measures (HM Government, 2020).

Steel is highly trade-intensive, the added cost reduces the ability of domestic firms to compete with international competitors and may instead lead to increased steel imports. The steel industry cannot pass unilateral costs on to their customers without losing market share due to the intensity of trade. Some steel products are commodities, which means they are priced globally and the suppliers are price takers. This can mean that steel suppliers often operate on low margins, making it difficult to pass on costs to end users. As a result, the UK steel industry is affected by different global carbon costs. Although carbon pricing is seen as the preferred policy to reduce greenhouse gas emissions, a high carbon price by itself will not stimulate a shift towards decarbonizing steel production. Without a unified global carbon price, additional policies need to be put in place alongside carbon pricing policies to ensure the steel industry will not be competitive by lower-priced, high-emissions imports. . As there are currently no safeguards (such as carbon border adjustments or carbon product standards) from foreign steelmakers exporting low-cost, high-carbon steel to the UK and European markets. The cost of carbon reduces the competitiveness of the industry.

Summary for BEIS Selection Committee Carbon Pricing Options The Government is considering three carbon pricing options at the end of the transition period: the UK's linked Emissions Trading Scheme (ETS), ETS UK independence and the Carbon Emissions Tax (CET). Since the average global carbon intensity for steel production is 1.85 tCO₂/tonne crude steel, compared with 1.6 tCO₂/tCS for the UK, an increase in imports is likely to lead to an increase in global greenhouse gas emissions. Thus, a higher carbon pricing in itself would only lead to a shift in emissions from the UK abroad, from direct UK emissions to imported emissions.

Steel is a global commodity and the pricing of carbon in the steel industry is influenced by global market dynamics, including supply and demand, exchange rates, trade policy and market competition. Environmental activism can influence carbon pricing in the steel industry by pressuring companies to adopt more sustainable methods. Technological advancements such as carbon capture, use and storage (CCUS) in low-carbon steel production methods can impact carbon pricing in the industry. In research related to the Covid-19 pandemic, Steffen et al. (2020) note that policies to adapt to shocks and crises should be introduced through designs and mechanisms that help mitigate risks. ro. They point out that carbon pricing policies are an example of policies that should be adapted in that sense.

The studies of Skovgaard et al. (2019), Sturner (1994), Speck (2014) indicate that the economic and financial crises, the need to reform the tax system and the need to mobilize financial resources have promoted the expansion of environmental taxation. The UK

government implements regulations and incentives that incentivize companies to reduce their carbon footprint resulting in lower carbon emissions in the steel industry and potentially driving down the prices of steel products. If policy diffusion does not support carbon emissions reductions but focuses on economic growth above all else, there could be fewer regulations and taxes resulting in higher carbon emissions from the steel industry, and higher prices of products. higher steel products due to lack of incentives or pressure to reduce emissions.

4. Discussion and Conclusion

First, Vietnam should establish a strategic governance structure to support the Ministry of Natural Resources and Environment, put in place measures to stabilize the market and provide support packages to help with a low-carbon transition. faster.

Second, policymakers need to consider the impact of large exemptions on important emissions sources, such as lowering the price of carbon or limiting coverage, which are closely related to strict policy and affect the effectiveness of climate change.

Third, tax authorities should make commitments and use communication devices that increase the visibility of carbon tax changes. Compensation may show up as withholding earnings on payslips, tax slips, or contributions to social insurance.

Fourth, Vietnam can devise policies to respond to shocks and crises through designs and mechanisms that help mitigate risks, typically combined tools, which can be of various types. taxes with an environmental integrity mechanism, such as recently proposed for the United States (Brooks and Keohane, 2020) or price-capped trading schemes, as recently proposed for Germany (Edenhofer et al., 2019).

Fifth, carbon pricing policies should be part of a policy mix in which different policy instruments help overcome specific barriers, possibly piloting in high-emissions sectors. , typically the steel industry.

Finally, the impact of carbon pricing on efforts towards net-zero emissions will require more research. Especially in terms of distributive and equitable consequences when groups of developing countries (such as Vietnam) with fewer resources to adopt decarbonization technologies, may face the risk of economic stress increasing.

APPROPRIATE WASTE-TO-ENERGY TECHNOLOGY FOR VIETNAM TOWARDS A CIRCULAR ECONOMY IN WASTE MANAGEMENT

MSc. Nguyen The Thong

thongnguyenthe15@gmail.com

Institute of Strategy, Policy on Natural Resources and Environment (ISPONRE)

Ministry of Natural Resources and Environment (MONRE)

Abstract

Municipal solid waste treatment (MSW) in Vietnam is facing notable challenges. Most of the MSW in Vietnam is being treated by landfill, causing many negative impacts on the environment. In order to improve solid waste management capacity, the Government of Vietnam has been offering many solutions including supplementing regulations and policies and finding suitable technological solutions. Waste-to-energy technology (WTE) is a type of technology widely applied worldwide when it contributes to the thorough treatment of non-recyclable solid wastes and creates an energy source for daily life and production. WTE incineration technology has become the key choice of developing countries with limited land and energy resources, including Vietnam. However, constructing a WTE plant with modern technology requires huge investment capital. On the other hand, investors still face many barriers, such as mechanisms, policies, and feasible conditions in deploying with specific conditions in Vietnam. Through the assessment of the current state of national policies and the analysis of challenges and opportunities in the process of practical application, this study has proposed appropriate solutions to promote appropriate WTE technology towards achieving the CE criteria in waste management.

Keywords: *Circular economy, waste management, waste-to-energy, municipal solid waste*

1. Introduction

Municipal solid waste originates mainly from human activities and business operations in urban and rural areas, is commonly found in communities, and occupies a large volume. In many developed countries, waste is converted into energy, such as electricity and heat for human use through advanced waste-to-energy technologies (WTE). According to the circular economy approach, waste can be treated as a valuable input material to generate energy for other business activities. In Vietnam, the prevalent method for disposing of waste is through landfill, and the utilization of incineration technology to convert waste into energy is not widely practiced. This not only results in the loss of waste resources, but also contributes to environmental pollution and the depletion of land resources for landfill purposes. Since 2020, the Vietnamese Communist Party and the State have been advocating for the adoption of a circular economy model to enhance production and business activities in various sectors, fields, and localities. In Vietnam, one of the most practical and feasible applications of the circular economy model is in the waste management industry, specifically

through utilizing WTE incineration technology. WTE incineration technology has become the key choice of developing countries with limited land and energy resources, including Vietnam. However, constructing a WTE plant with modern technology requires huge investment capital. On the other hand, investors still face many barriers, such as mechanisms, policies, and feasible conditions in deploying with specific conditions in Vietnam. One question that arises is whether this technology is an effective and timely solution for waste management towards a circular economy in the coming time. On that basis, the study of applicability towards finding solutions to promote the application of WTE incineration technology with recover electricity in Vietnamese conditions is extremely useful and necessary in the context of encouraging the application of a circular economy model.

2. Method

This study was carried out based on a combination of the following main methods:

(1) Desk research: The process of researching and developing policy documents related to waste management and circular economy to assess the suitability of WTE technology for conditions and situations in Vietnam

(2) Field survey: This study conducted a survey discussed directly with representatives of the WTE incineration plant in Can Tho, Vietnam, to assess the actual application status, difficulties and challenges has been faced to identify and propose necessary solutions to promote alternative technologies for landfill in Vietnam.

(3) SWOT method: The SWOT analysis method is a strategic tool to assess strengths, weaknesses, opportunities, and threats for programs and projects to assist decision-makers in the process. management policy promulgation. This method is widely used by researchers in the energy field and is particularly relevant to studying energy recovery from solid waste. This study also analyses the direction of strengths and weaknesses, opportunities and challenges in the application of WTE technology in Vietnam to determine the appropriateness of this type of technology in the context, conditions and current policy situation in Vietnam.

3. Results

3.1. Background

Different types of WTE technologies exist, such as incineration with energy recovery, gasification, composting, pyrolysis and anaerobic digestion, in fact, due to the diverse treatment characteristics of different types of waste and the ability to process large volumes of waste at the same time, incineration with energy recovery is considered to be the most widely applied technology in the world.

Around the world

According to statistics of the United Nations, in developing countries, more than 90% of waste collected goes to landfills, while more than 80% of plants using thermal WTE technology are located in developed countries, led by Japan, the US, France and Germany (UNEP, 2019). Besides, 15% of domestic waste generated worldwide is treated with WTE

technology. Energy recovery incineration technology is receiving much attention in developing countries due to its potential for energy recovery and waste reduction. WTE incineration technology to recover energy is appearing more in Asian countries such as China, Thailand, Philippines, Indonesia and Myanmar. It is forecasted that more than 200 waste incineration plants to recover energy are under construction and will come into operation in the period 2020 and 2030. Due to the development trend of countries, countries are gradually shifting to a circular economy model, these countries are tending to shift from the traditional incineration model to incineration with recover energy and other types of waste incineration.

Figure 1. Percentage of MSW incinerated to recover energy in countries around the world

Source: EPA (2019)

As of 2019, in Europe, WTE plants in Europe produce enough electricity to power 19 million people and heat 15 million people a year. In addition, about 10% of the energy produced from WTE plants is supplied to heating systems throughout Europe (CEWEP, 2022)

According to EIA statistics, WTE plants in USA generate about 14,000 GWh of electricity per year in the US. Although this amount of electricity accounts for less than 1% of all electricity produced in the United States, these facilities provide a stable and continuous electricity load to the national electricity system. At the beginning of 2022, 60 WTE plants in the US were put into operation, with a total electricity production of 2,051 MW. (EIA, 2023)

In Vietnam

The WTE incineration technology has been known in Vietnam for over 10 years. This is seen as the direction for sustainable development to reduce waste and environmental pollution. On that basis, developing WTE incineration technology to recover electricity is a main goal in some localities when attracting the private sector to participate in waste treatment. Initially, first and second WTE incineration plants which were put into operation

were recorded in Can Tho (2018) and Hanoi (2022). While many localities also organize the implementation of investment procedures for the construction of waste incineration plants for power generation such as: Vinh Tan WTE plant in Dong Nai province (treatment capacity of 600 tons/day with 30 MW electricity generation); WTE plant in Tram Than, Phu Ninh, Phu Tho province (capacity 500 tons/day); two WTE incineration plants in Cu Chi, Ho Chi Minh City (of Vietstar and Tam Sinh Nghia, each with a capacity of 1,000 tons/day). However, the WTE incineration technologies that have been deployed in Vietnam still face many difficulties in implementation and replication due to various reasons such as: not meeting legal procedures, limited resources, limited treatment costs, waste segregation at source or the amount of insufficient volume of waste.

Can Tho waste incineration plant for power generation EB Can Tho Environmental Energy Co., Ltd. invests in an area of 5.3ha with a design capacity of 400 tons of waste/day. The plant has been in operation since September 2018 and was connected to the national grid with a capacity of 7.5 MWh.

Soc Son power plant, Hanoi (about 17.51 hectares on the area of Nam Son landfill). It is owned, invested, managed and operated by Thien Y Hanoi Environmental Energy Joint Stock Company to treat waste by incineration with energy recovery with a maximum capacity of 4,000 tons per day. On July 25, 2022, the plant officially connected to the national power grid with a generating capacity of 15MW from waste incineration in phase 1 and a total capacity of 75MW. Currently, the plant is operating stably in phase 1 with a waste treatment capacity of 800-1,000 tons/day.

Since the Law on Environmental Protection 2020 was promulgated, Vietnam has officially issue definition of circular economy into the legal document system. Following that, policies on the CE were issued by Decree No. 08/2022/ND-CP dated January 10, 2023, which stipulates the criteria, roadmap and mechanism to encourage the implementation of the CE in Vietnam. Additionally, due to more than 70% of domestic waste in Vietnam is treated by landfill method (MONRE, 2019), the Government of Vietnam has added policies such as waste segregation at source¹, collect waste treatment fee by volume² starting from 2025. The regulations aim to promote waste management capacity towards the application of CE.

3.2. The impact of WTE technology in the process of sustainable development

The WTE incineration technology is assessed as the most feasible and is supported by the Government of Vietnam. In the implementation and application in the context of sustainable development, the positive and negative impacts of this technology in practical application are assessed according to Table 1:

¹ Clause 1, Article 75 of the Law on Environmental Protection 2020

² Clause 1, Article 79 of the Law on Environmental Protection 2020

Table 1. Positive and negative impacts, and main requirements for waste incineration technology for power generation

Aspects	Positive impacts	Negative impact
Technological	Effective in reducing landfill waste, disease control and restoring energy (electricity and heat)	Use complex technology (in both construction and operation)
Environmental	Save land resources for burial purposes.	Ash and fly ash must be handled appropriately due to the risk of negative health effects
GHG emissions	Contribute to GHG mitigation in 2 ways: (1) remove methane from landfill when using alternatives (2) use energy generated from waste as alternative energy	- Compared to recycling and reuse sources, waste incinerators generate more GHG emissions
Economic	The generated energy can be sold or used	Operation and construction costs are very expensive. Profits from the sale of electricity and other types of recycled products are not enough to cover the operating costs of the waste treatment facility.
Resource aspect	- Electricity, steam and heat can be recovered.	- Incinerators that generate electricity require a steady stream of waste, which is a major obstacle in preventing waste generation. - Power production efficiency is limited due to acid emissions - There are fewer ways to utilize steam and heat than electricity
Social aspects and other aspects	WtE burning is effective in preventing infections from viruses and bacteria and controlling the spread of waste-related infections. WtE incineration facilities can act as an alternative to backup power, especially in the event of a catastrophic outage. Burning waste to generate electricity plays an important role in the circular economy model.	Local residents often express their opposition to the establishment of incinerators due to concerns regarding potential health risks, environmental contamination, unpleasant odors, diminished land values, and dissatisfaction stemming from a lack of clear and thorough explanation regarding the rationale behind the chosen location of the treatment plant and other reasons (Chen Liu et al., 2020)

3.3. Aspects of WTE technology that meet circular economy criteria

According to the "9R" framework of the Circular Economy (Figure 3), it can be seen that WTE technology applied in waste treatment ranks the last position "R9", which stands for "Recover". However, in fact, relatively low source separation capacity relatively low co-exists with a significant amount of waste generated on a daily basis, while the capacity to recycle and reuse waste only accounts for a minor portion of the total amount of waste generated, especially in developing countries such as Vietnam, Thailand, or India. Therefore, in order to thoroughly treat the entire amount of solid waste generated, the Recovery option is still more optimal than disposing directly to the landfill.

Figure 2. Waste management hierarchy
 Source: Article 4 of the revised Waste Framework (Directive 2008/98/EC)

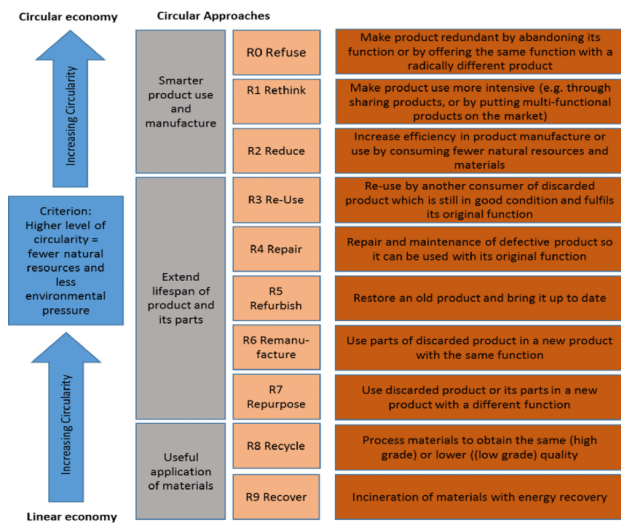

Figure 3. "9R" framework of circular economy
 Source: Potting et al. (2017, p.5)

Specific contributions of WTE technology to the implementation of the Circular Economy in Vietnam:

- Landfill waste reduction: Using WTE incineration technology, the majority of combustible waste and non-recyclable pollutants are handled rather than transferred to landfills. WTE plants burn two types of MSW. One is composed of biological elements, biogenic substances including paper, packaging, plastic, and food waste. The other is constructed of synthetic materials like plastic and rubber. The percentage of non-biological materials burnt has grown over the previous few years as more plastic, less paper, and paper products are discarded.

- Secondary Materials Recovery: After the combustion process is completed, the output waste including ashes and furnace bottom slags, after being verified to be unarmful and compliant with environmental standards, is typically transferred to landfills or optimized through recycling and reuse for cement binder (CBM), production of building materials (brick, cement or concrete beams) or even mine leveling exploited soil and rock mines to improve economic efficiency and address environmental problems.

- Energy Recovery: After combustion, energy is produced in the form of heat, electricity, or both. WTE plants offer a constant supply of renewable energy in addition to intermittent renewable energy sources like solar or wind and also assist with the handling of non-recyclable trash. Thermal energy is used for heating, particularly in places like Switzerland, while the generated electricity is directly used as a renewable energy source.

- Carbon emission recovery: WTE technology can be combined with GCUS technology to capture and store carbon in the waste treatment process to create materials and goods. In many nations throughout the world, carbon pricing is regarded as one of the efficient policies for achieving GHG emission reduction goals. In particular, the European Union Emissions Trading Market (EU ETS) is the largest multination market; in Korea, the use of carbon offset credits may be used to meet up to 10% of participant obligations; in China, a pilot program for seven carbon markets has been established³; and some nations, including Taiwan, Thailand, and Vietnam, are planning to implement carbon pricing policies. WTE plants can therefore benefit from carbon policies and be considered a source of carbon credits under the Clean Development Mechanism or other carbon offset credits schemes (ADB, 2020).

The suitabilities for Vietnam's orientation of implementing the Circular Economy model:

- The use of WTE technology complies with the "energy recovery" requirement, one of the CE criteria listed in Article 138 of Decree No. 08/2022/ND-CP. The regulation specifically lists "energy recovery through waste incineration" as one of the measures that investment project owners have to take for meeting the CE criterias.

- Article 140 of Decree No. 08/2022/ND-CP, which outlines a mechanism to promote the implementation of the CE, states that the Government prioritizes investments in scientific research, application development, technology transfer, and equipment production that supports the implementation of the CE.

- In Decision No. 31/2014/QĐ-TTg dated 5/5/2014, the Vietnamese government also established mechanisms to encourage the development of power production projects using solid waste in Vietnam. According to this, the price for power production projects that directly burn solid waste is VND 2,114/kWh, higher than the retail electricity price applied from 2023 at VND 1,728/kWh.

- In accordance with the Government's pledge at the United Nations Climate Change Conference (COP26) to achieve net zero emissions by the year 2050, Vietnam also has regulations on the development of a carbon market (based on Clause 35, Article 3, and Clause 1, Article 139 of the Law on Environmental Protection 2020). In addition to energy recovery, the use of WTE technology can support national carbon credits.

³ In 2013 and 2014, 7 carbon markets were tested in 5 cities and 2 provinces with 57 million tons of carbon traded.

3.4. Appropriate waste-to-energy technology for Vietnam towards a circular economy in waste management

3.4.1. Challenges

From the above analysis results, the challenges identified in the implementation and application of WTE incineration technology in Vietnam are as follows:

- ***Complicated and lengthy investment procedure:*** The success or failure of WTE technology depends a lot on cooperation. stakeholders and the current status of the local institutional, policy and legal framework. Stakeholders in waste incineration projects often have conflicting interests based on environmental and economic issues (World Bank, 2000). Due to WTE technology is transferred from abroad, investors need to carefully study the necessary procedures for appraisal and evaluation of the project according to the provisions of the Law on Technology Transfer 2017. In addition, WTE is also considered a type of technology that impacts the environment, as a result, this technology also needs to carry out procedures related to the environment such as Environmental Impact Assessment (EIA) and other related procedures. In fact, the investment procedure for WTE plant in Vietnam is relatively complicated and lengthy, requiring the approval of various ministries and branches, including EIA, electricity source development planning; lacking and inconsistent regulations on incentives for WTE technology; technology appraisal procedures.

- ***High moisture content of waste:*** Obviously, the characteristics of MSW is an extremely important criterion for all types of treatment technologies in general and WTE technology in particular. As recommended by the United Nations Environment Program, for efficient operation of WTE incineration technology. The calorific value of waste should be at least 7 MJ/kg (equivalent to 1673 Kcal/kg) on average, and never fall below 6 MJ/kg (equivalent to 1433 Kcal/kg). A very important issue when operating a waste incinerator is the calorific value of the waste. The higher the calorific value of the waste, the higher the combustion temperature. That reduces the pressure on the operating process of raw materials and fuel, helps the combustion process to occur thoroughly and reduces the load on the gas treatment process. Vietnam's solid waste is characterized by high moisture content (ranging between 65 - 95%) and low calorific value (ranging from 900 - 1,100 Kcal/kg) (MONRE, 2019).

- ***Unsorted waste at source:*** The MSW in Vietnam has a high organic content and is not sorted at source. The unsorted waste leads to difficult and costly treatment, high humidity conditions in Vietnam will consume a lot of fuel (oil) for the incinerator. There have been many projects and researches aimed at improving the waste sorting capacity in urban as well as rural areas in Vietnam, but the results have not been as expected.

- ***Risk of dioxin and furan emission:*** The operation process of WTE plants needs to strictly comply with technical regulations and periodically monitor from the environmental management agency. Although with the current state of air pollution control technologies, it is possible to treat and reduce emission concentrations below the allowable standard, the risk of dioxin and furan emissions exceeding the allowable standard has been recognized in many countries such as China, India and the Netherlands. Therefore, the operation and maintenance

activities at WTE plants are not guaranteed in terms of quality and quantity can lead to high levels of dioxin emissions that negatively affect the human health and the environment.

3.4.2. Opportunities

- ***Contribution to Sustainable Development Goals (SDGs):*** developing WTE technology not only reduces landfill waste but also creates a continuous renewable energy, which directly contributes to progress of SDG implementation such as SDG 11 “sustainable cities” and SDG 7 “sustainable energy”. Currently, the Government of Vietnam has also issued a National Plan to implement 17 SDGs in Decision No. 622/QĐ-TTg dated May 10th, 2017.

- ***Enhance waste management capacity:*** Promoting MSW treatment by WTE technology can directly support a list of goals outlined in the Integrated Solid Waste Management Strategy until 2025, vision to 2050 of the Government was approved in Decision No. 491/QĐ-TTg dated May 7th, 2018 such as “enhanced processing combined with energy recovery” or “the rate of MSW treated by landfilling is less than 30% of the collected waste until 2025”. In addition, the application of WTE technology is also completely consistent with the viewpoint that “The generated solid waste must be managed in the direction of being considered a natural resource”.

- ***Contribution to the national energy load:*** According to the revised Power Plan VII to 2025, Vietnam needs to add about 6,000MW annually from now to 2025. Meanwhile, MSW are an abundant and readily available source of raw materials involved in this field. As a result, it can be clearly seen that WTE technology in Vietnam has a potential market and few competitors.

- ***Profits for investment enterprises:*** In the process of waste treatment, enterprises investing in WTE incineration technology in Vietnam receive treatment costs through local waste treatment service prices and gain profits through electricity price incentives according to the Government's regulations. Furthermore, along with regulations on the responsibility to buy electricity from WTE projects, there are also regulations on incentives for investment capital and tax; land incentives. In addition, the investor can also increase profits from the sale of recyclable by-products such as ash, slag and other recycled products from the input waste sorting process.

3.5. Recommendations on applying WTE incineration technology to implement the circular economy model in Vietnam

Based on global experience and the practical conditions of Vietnam, the following suggestions should be considered to ensure effective implementation of waste incineration technology to recover energy:

First, the circular economy implementation plan for energy recovery waste incineration should be integrated into various planning documents, including the national master plan, regional plan, industrial and sectoral plans, as well as provincial plans. This is because the national master plan has already been issued, while regional, industrial, and sectoral planning have been implemented, and provincial planning is currently in the process

of being implemented, appraised, and approved. Therefore, integrating the circular economy model for converting waste into energy based on incineration technology is an essential foundation for future implementation during the 2021-2030 period, with a vision towards 2050.

Second, based on the existing plan, designing a circular economy model for waste-to-energy incineration is of great significance. This involves careful consideration of factors such as the necessary scale of waste, appropriate technology, optimal location and area, and economic and technical viability in each region and locality. By analyzing the advantages and limitations of waste-to-energy incineration technology for each area, a suitable model can be developed. For instance, in Shenzhen, China, waste-to-energy incineration plants are typically located at landfill sites. Similarly, the first waste incinerator in Hanoi, which generates electricity, is situated at the Nam Son landfill and waste treatment area in the Soc Son district.

Third, call for investment capital and open bids to implement the circular economy model of waste incineration and energy conversion. This bidding process will ensure the selection of the most effective investors. Although the private sector has proven to be highly effective in investment and implementation, in the case of waste-to-energy incineration, the profit margins may not be high, as discussed earlier. Therefore, appropriate policies are necessary to encourage private-sector investment. Public-private partnerships (PPP) are also a feasible option for waste treatment and circular economy model in waste-to-energy incineration, which have been implemented by many countries. Vietnam should also consider and implement the PPP model in the circular economy plan for waste-to-energy technology.

Fourth, unlike the previous model of burning waste to produce energy, waste-to-energy incineration in the circular economy model must ensure the full recovery of energy, solid waste and exhaust gases after combustion. These recovered materials can then be used as input sources for other business activities. Many countries that have implemented this model have learned this valuable lesson.

Fifth, remove any obstacles in the mechanisms, policies, and management of implementing the circular economy model that uses waste incineration technology for energy conversion. Since this model involves various policies related to the environment, energy, business, land,...., it is essential to review and address relevant policies and difficulties to ensure effective implementation. The resolution of policy and implementation stages should align with the laws and chief policies of the Communist Party regarding the circular economy.

4. Discussion and Conclusion

In a developing country like Vietnam, an appropriate technology is when it meets a list of criteria, including the lowest cost, technical and legal feasibility, effective pollution treatment, and community acceptability. Energy recovery from MSW from the point of view of the CE is in line with the development trend of the world in the context of current globalisation. Therefore, in the long run, this investment direction will continue to receive the attention of the Vietnam Government and appropriate development policies. To achieve

a circular economy model in waste management, waste incineration technology can be utilized to convert waste into energy, thereby addressing the current issue of mainly landfilling waste. Based on the experiences of other countries, several waste incineration projects that generate electricity have been implemented in Vietnam. Therefore, applying a circular economy model that utilizes waste incineration technology to produce energy is feasible in Vietnam in the near future. However, despite the advantages, the implementation process may face certain difficulties, and the recommendations mentioned above need to be carefully considered and tailored to the reality in Vietnam.

ENERGY TRANSITION FOR 2050 NET ZERO IN VIETNAM: OPPORTUNITIES, CHALLENGES AND POLICY IMPLICATIONS

Assoc. Prof. Dr. Vu Thi Hoai Thu

thuvh@neu.edu.vn

National Economics University, Hanoi, Vietnam

Abstract

Reaching net zero emissions target by 2050 established in COP 26 is the inevitable development pathway of the world in the future. Putting the energy sector on a pathway to 1.5°C to achieve net zero emission target is critical and energy transition plays a vital role. Viet Nam demonstrated a strong commitment to reduce greenhouse gas emissions to net zero by 2050 which places the energy sector a key role to play. In addition to opportunities to restructure its economy and align climate finance flows for energy transition, the energy sector in Viet Nam have encountered many challenges, including heavy dependence on fossil fuels in the total primary energy supply, underdeveloped renewable energy, inefficient energy consumption and increased energy imports. To achieve a just and sustainable energy transition in Viet Nam in the coming time, it is necessary for Vietnam to facilitate rapid renewable energy deployment by improving the regulatory framework, build an attractive investment landscape for private capital to finance energy transition projects, improve energy system resilience by investing in the power grid's capacity and expanding energy-storage facilities for renewable energy, accelerate implementation of energy efficiency plans including effective pricing policies, reform of electricity tariffs, develop natural gas to power as a transition fuel and promote consumer participation and build the local workforce required for the energy transition, paying particular attention to the livelihoods of vulnerable populations.

Key words: *Climate change, energy transition, net zero emission, sustainable development.*

1. Introduction

There is now strong scientific evidence that climate change is happening and being accelerated by human activity. The world is getting warmer. Global surface temperature was 1.09°C higher in 2011-2020 than 1850-1900 and global mean sea level increased by 0.20m in 1901-2018 (IPCC, 2021). Climate risks and extreme events have wide-ranging impacts across multiple dimensions of the economy. Climate change is a threat to socio-economic development, thus combating its negative impacts is vitally important for all countries. In addition, climate change presents a wide range of opportunities for countries to invest in green growth and low-carbon economy.

Reaching net zero emissions by 2050 is the inevitable development pathway of the world in the future and is realized mainly through a robust low-carbon transition and a low-carbon development pathway which has been established since the 26th Conference of the

Parties to the United Nations Framework Convention on Climate Change (COP26). By transitioning to a low-carbon economy built on energy efficiency, renewable energy, and sustainable production and consumption patterns, countries can combat climate change while at the same time strengthen the economy competitiveness and bring socio-economic co-benefits.

Putting the energy sector on a pathway to 1.5°C to achieve *net zero emissions by 2050* as committed at COP26 is critical. Transition to a low-carbon energy pathway is widely acknowledged as an inevitable trend in the future through increasingly shifts away from carbon emitting fossil fuels, enhancement of energy efficiency, renewable energy, and low-carbon technologies. Converting energy from fossil fuels to clean and renewable energy sources is a great opportunity for countries to promote economic restructuring towards sustainability, seize huge opportunities to enhance the economy competitiveness as well as take advantage of trade and investment cooperation for a sustainable future.

Over the past years, the energy sector has made a positive contribution to the country's socio-economic development in Vietnam. Economic growth requires secure and affordable supply of energy to all economic sectors. Viet Nam has a variety of domestic primary energy sources such as coal, oil, natural gas and hydro power which play an important role in ensuring energy security for economic development in the past two decades. However, the energy sector in Viet Nam have encountered many challenges that needs to be addressed to secure the supply of energy sources in the long term while at the same time reducing negative environmental impacts and controlling greenhouse gas emissions.

This paper presents an overview of energy transition in the context of achieving 2050 net zero emission target, analyses opportunities and challenges of energy transition in Vietnam and proposes some policy implications for a sustainable and just energy transition in Vietnam in the near future.

2. Literature Review and Theoretical Framework

There are currently different concepts of net zero emissions used by different actors with different purposes. In some cases, specific terms (e.g. net zero greenhouse gas (GHG) emissions or carbon neutrality) are used to distinguish between different emission targets (e.g. in terms of the coverage of GHGs - all GHGs or carbon dioxide only). In other cases, terms are used interchangeably (e.g. climate neutrality vs. carbon neutrality). Differences in terminology reflect different interpretations of the concept of net zero emissions. Net zero emission is a state where the sum of all anthropogenic emissions and removals is zero (IPCC, 2021). Net zero emission targets are being defined in a variety of ways - the most important aspect from a global geophysical perspective being whether they cover all GHGs or carbon dioxide (CO₂) only (Rogelj et al. 2015, cited in UNEP, 2021).

In the past few years, "net zero" has been launched to a central pillar of efforts to support the long-term temperature goal of the Paris Agreement adopted by 196 Parties at COP 21 in Paris, on 12 December 2015 and entered into force on 4 November 2016. The Paris Agreement marked the incorporation of the net zero concept into international policy.

The idea of achieving net zero emissions was enshrined in Article 4.1 of the 2015 Paris Agreement. The inclusion of “net zero” in the Paris Agreement and the rationale for reaching net zero emissions was further supported by the 2018 Intergovernmental Panel on Climate Change (IPCC) Special Report which highlighted that to limit warming to 1.5°C above pre-industrial levels with no or limited overshoot, global CO₂ emissions should reach net zero around midcentury (IPCC, 2018). Net zero emissions are reiterated in the 2021 Working Group I contribution to the IPCC’s Sixth Assessment Report (IPCC, 2021). These could be seen to provide a common foundation for the cascade of net zero commitments put forward by countries and non-state actors in recent years. As of June 2022, at least 1,180 entities have a net zero target of some description, including 128 countries and self-governing territories, 235 cities, 115 states and regions, and 702 publicly listed companies from the Forbes Global 2000. The spotlight falls on companies (65 percent), regions (84 percent) and cities (80 percent) that are yet to pledge net zero targets. National government targets (including the European Union and Taiwan) represent 91 percent of global GDP (PPP), up from 68 percent in Taking Stock 2021, accounting for 83 percent of global GHG emissions, up from 61 percent and representing 80 percent of the global population, up from 52 percent (Net Zero Tracker, 2022).

Energy plays a critical role to a modern economy to heat and light homes, to help travel and to power businesses. Primary energy sources include fossil fuels, renewable energy, and nuclear energy. Secondary energy sources include electricity, heat and fuels (gasoline and refined oil products). Fossil fuels are known as carbon-based fuels from fossil hydrocarbon deposits, including coal, oil, and natural gas (IPCC, 2021). Renewable energy is derived from natural processes that are replenished constantly (IEA, 2002). Nuclear energy is a form of energy released from the nucleus, the core of atoms, made up of protons and neutrons (IEA, 2022).

Putting the energy sector on a pathway to 1.5°C to achieve net zero emission target by 2050 as committed at COP26 is critical and energy transition plays a vital role. Energy transition is a significant structural change in an energy system regarding supply and consumption. Energy transition generally refers to the global energy sector’s shift from fossil-based systems of energy production and consumption, including oil, natural gas and coal to renewable energy sources (e.g. wind and solar). Currently, a transition to sustainable energy (mostly renewable energy) is underway to limit climate change.

The current energy transition is driven by a recognition that global greenhouse-gas emissions must be drastically reduced. Climate watch data shows that energy production and consumption are responsible for 76% of annual human-caused greenhouse gas emissions as of 2018. A rapid energy transition to very-low or zero-carbon sources is required to mitigate the effects of climate change since coal, oil and gas combustion account for 89% of CO₂ emissions. This process of energy transition involves phasing-down fossil fuels and re-developing whole systems to operate on low-carbon energy sources.

The shift towards low-carbon energy systems is taking place in all industry sectors and across all regions around the world. The world needs to give up fossil fuels, particularly

coal, and move to a lower-carbon energy sources that embraces renewables and nuclear power. In addition, energy transition has to address the three daunting challenges of security, affordability and sustainability, known as the Energy Trilemma, which challenges governments, cities and organizations alike. It demands solutions that can tackle all three problems together. Addressing one dimension of the trilemma in isolation will make the others worse. The trilemma means that policy should never focus on one single aspect and should look at the three challenges in a balanced way. Lower-carbon energy solutions such as wind, solar, geothermal, hydro, marine and nuclear power, net zero energy schemes, micro grids, and heating all have a part to play in addressing the Energy Trilemma.

Energy transition to a low-carbon and net-zero CO₂ energy systems entail a substantial reduction in overall fossil fuel use, minimal use of unabated fossil fuels, and increased use of Carbon Capture and Storage in the remaining fossil system; enhanced electricity systems that emit no net CO₂; widespread electrification of the energy system including end uses; increased energy carriers such as sustainable biofuels, low-emissions hydrogen, and derivatives in applications less amenable to electrification; enhanced energy conservation and efficiency; and greater physical, institutional, and operational integration across the energy system (IEA, 2021; IRENA, 2022; IPCC, 2022). The most appropriate strategies depend on national and regional circumstances, including enabling conditions and technology availability.

Accelerating the energy transition is an urgent and challenging task. It will require farsighted choices, discipline, wise investments and enhanced international cooperation on technology development and finance. Aligning the energy sector on a pathway to 1.5°C can also help address other important global concerns such as energy price volatility and energy security as well as bring economic and social benefits to consumers and businesses around the world.

3. Method

The study uses secondary data and information which were collected from a variety of sources, including reports from Vietnam's Government Statistics Office, Vietnam's Ministry of Natural Resources and Environment, books, journals, papers, and research reports of individuals and organizations related to the research topic.

A desk-based approach combined with statistical, descriptive, and comparative methods are applied to address the research question.

4. Results

4.1. Energy supply and consumption in Viet Nam

Over the past years, Vietnam has achieved remarkable socio-economic achievements. The energy sector has made a positive contribution to the country's socio-economic development. Economic growth requires secure and affordable supply of energy to all economic sectors. The energy sector must be able to attract the capital required to expand energy infrastructure and to secure the supply of energy sources in the long term while at the same time reducing negative environmental impacts and controlling greenhouse gas emissions.

Table 1. Total primary energy supply in Vietnam in 2010-2019*Unit: KTOE*

	2010	2015	2016	2017	2018	2019
1. Fossil fuels	39,145	53,796	55,578	56,005	67,031	78,536
	74.6%	80.3%	80.4%	78.5%	81.7%	85.1%

Total	52,490	66,964	69,166	71,349	82,039	92,329
	100%	100%	100%	100%	100%	100%

Source: Institute of Energy (2020)

Fossil fuels are the backbone of the total primary energy supply (TPES) in Viet Nam. The share of fossil fuel supply increased from 74.6 percent of TPES in 2010 to 85 percent in 2019. This is followed by renewable energy (11 percent of TPES in 2010 to 13.9 percent in 2019). Coal plays an important role in TPES as the share of coal grew from 28 percent (in 2010) to 49 percent (in 2019) (Table 1). This trend is expected to continue in the future as the domestic supply of hydro power and biomass seems to be unable to meet the increasing demand.

Table 2. Final energy consumption in Vietnam in 2010-2019*Unit: KTOE*

	2010	2015	2016	2017	2018	2019
1. Fossil fuels	24,747	27,094	30,924	31,307	35,777	38,835
	58.6%	54.0%	59.9%	59.1%	61.0%	61.8%
Coal	9,893	11,457	9,393	9,207	12,612	15,362
	23.4%	22.8%	18.2%	17.4%	21.5%	24.4%

	34.0%	31.2%	39.8%	40.0%	38.0%	35.9%

	2010	2015	2016	2017	2018	2019
Natural gas	493	1,458	955	890	901	919
	1.2%	0.0%	1.8%	1.7%	1.5%	1.5%
2. Non-commercial energy	7,196	4,064	2,601	2,081	1,457	891
	17.0%	8.1%	5.0%	3.9%	2.5%	1.4%
3. Renewable energy	2,990	3,823	4,304	4,572	4,787	5,013
	7.1%	7.6%	8.3%	8.6%	8.2%	8.0%
4. Electricity	7,278	10,986	13,832	15,007	16,619	18,095
	17.2%	21.9%	26.8%	28.3%	28.3%	28.8%
Total	42,211	50,169	51,661	52,967	58,639	62,833
	100%	100%	100%	100%	100%	100%

Source: Institute of Energy (2020)

In term of the structure of final energy consumption, fossil fuel consumption (coal, oil products and natural gas) accounted for 58.6 percent in 2010 and increased to 61.8 percent in 2019, followed by renewable energy (7.1 percent in 2010 to 8 percent in 2019) (Table 2). Generally, fossil fuel consumption accounts for a large proportion of the energy consumption in Viet Nam.

4.2. Greenhouse gas emissions in Viet Nam

The total amount of greenhouse gas (GHG) emissions in Viet Nam has increased over the years as a result of fast economic growth. In 2016, GHG emissions in energy sector account for 65 percent, followed by industrial processes (14.6 percent), agriculture-forestry and land use (13.9 percent) and waste sector (6.5 percent) (Table 3). It can be seen that GHG emissions from energy and industrial processes accounted for the largest shares and also increased at the fastest growth. Therefore, cutting GHGs emissions from energy and industrial processes plays a critical role. In addition, it is necessary to increase the carbon absorption through nature-based solutions.

Table 3. GHG emissions in Viet Nam in 1994-2016 (MtCO_{2e})

Sectors	1994	2000	2010	2013	2014	2016
Energy	25.6	52.8	141.1	151.4	171.6	205.8
Agriculture	52.4	65.1	88.3	89.4	89.7	83.5
Industrial processes	3.8	10.0	21.2	31.7	38.6	46.1
LULUCF	19.4	15.1	-19.2	-34.2	-37.5	-39.5
Waste	2.6	7.9	15.4	20.6	21.5	20.7
Total	103.8	150.9	246.8	259.0	284.0	316.7

Source: MONRE (2014), MONRE (2017), MONRE (2020)

The country's rapid economic growth, urbanization, and industrialization over the last 30 years have been powered by a coal-dependent energy supply that creates significant GHG emissions. MONRE data showed that emissions from energy sector went up the most rapidly, from 25.6 MtCO_{2e} (in 1994) to 151.4 MtCO_{2e} (in 2013) and reached 205.8 151.4 MtCO_{2e} (in 2016) due to the rapid increase in energy demand. Energy sector emits the largest proportion of GHG emissions in Vietnam, accounting for 65.5 percent of total GHG emissions in Vietnam in 2016.

Viet Nam is one of the most GHG-intensive economies in East Asia (measured as emissions per unit of output) in Asia, similar to Indonesia's, but much higher than China's or the Philippines'. In absolute terms, Vietnam's GHG emissions - 364 million tonnes of CO_{2e} in 2018 - amount to no more than 0.8 percent of global emissions, on par with Malaysia, Thailand, France, and the United Kingdom. GHG emissions per capita were 3.81 tonnes CO_{2e} in 2018, up from 0.79 tonnes in 2000, but still relatively low by regional and global standards (World Bank, 2022).

4.3. Climate change policies and Net Zero Emission target in Viet Nam

The Government of Viet Nam has made remarkable efforts to develop and implement national laws, strategies, and action plans to promote a low-carbon development pathway, reduce vulnerability to the impacts of natural disasters and climate change, and enhance green growth and sustainable development, notably the Environmental Tax Law (2010), Law on Efficient Use of Energy (2010), Law on Natural Disaster Prevention and Control (2013), the Law on Meteorology and Hydrology (2015), the Law on Environmental Protection (2020), the Party's Resolution 24/NQ-TW dated June 3, 2013 on climate change response, natural resource management and environmental protection, the Party's Resolution No. 08/NQ-CP dated January 23, 2014 on Action Plan to implement Resolution No. 24 -NQ/TW dated June 3, 2013 of the 11th Party Central Committee, National Green Growth Strategy (2012, 2021), National Climate Change Strategy (2011, 2022), and the National Action Plan for the implementation of the 2030 Sustainable Development Program. Climate change response efforts and initiatives in Vietnam have also been reflected in Vietnam's Agenda 21 on Sustainable Development (2004), the National Strategy and Plan on Disaster Management and Mitigation (2001-2020, 2021-2030). Response to climate change has also been included in the Socio-Economic Development Strategy (2011-2020, 2021-2030).

Viet Nam also fulfil international commitments on climate change. Vietnam signed the UNFCCC in 1992 and ratified it in 1994; signed the Kyoto Protocol in 1998 and ratified it in 2002. Vietnam submitted National Communications to UNFCCC (2003, 2010, 2019) and Biennial update reports (2014, 2017, 2020). INDC (Intended Nationally Determined Contribution) was submitted in 2015. Recently, Vietnam signed the Paris Agreement on the Climate in April, 2016; approved the Paris Agreement in November, 2016 and updated its NDC in 2020.

At the UN Climate Change Conference in Glasgow in November 2021 (COP26), the Viet Nam Prime Minister demonstrated the country's strong commitments to reforms at

COP26, including an ambitious target of reducing emissions to net zero by 2050. Also at COP26, Vietnam joined more than 100 countries in pledges to halt deforestation by 2030 and to slash methane emissions by 30 percent from 2020 levels by 2030. Vietnam has further committed to ending all investment in new coal power generation, scaling up deployment of renewable energy, and phasing out coal power by the 2040s. These commitments go beyond those included in the Nationally Determined Contribution (NDC) update submitted in 2020 under the UNFCCC.

The National Climate Change Strategy to 2050, approved at the Decision No. 896/QĐ-TTg of the Prime Minister dated July 26, 2022, sets the overall objective to proactively and effectively adapt to climate change, reduce GHG emissions to net zero emission by 2050 and deal with vulnerabilities and risks caused by climate change. The Strategy also aims to make active and responsible contributions to the international community in protecting the Earth's climate, take advantage of opportunities from climate change response to transform growth models, as well as improve the competitiveness of the economy, contributing to the realization of the developed and high-income country target by 2045. Emphasis is placed on mobilizing resources from organizations, enterprises, individuals, and international resources for climate change combat, developing financial mechanisms and carbon markets, as well as promoting investments towards a low-carbon economy. Achieving net zero emission target by 2050 is legalized in the National Climate Change Strategy to 2050.

5. Discussions and Conclusion

5.1. Policy implications

Laws, policies, and strategies for energy development have been enacted over years in Viet Nam, for example, the Electricity Law (2004, revised 2012), the Law on Petroleum (1993, 2000, 2008, 2013), Decision No. 1264/QĐ-TTg dated October 1, 2019 on National Electricity Development Plan for the period 2021-2030, Decision No. 2068/QĐ-TTg dated November 25, 2015 approving Vietnam's Renewable Energy Development Strategy to 2030 with a vision to 2050, the National Target Program on Energy Saving and Efficiency (2006-2010, 2012-2015, 2019-2030) and the Resolution No. 55-NQ/TW dated February 11, 2020 on the Orientation of the National Energy Development Strategy of Vietnam to 2030, with a vision to 2045.

In general, Viet Nam has a variety of domestic primary energy sources such as coal, oil, natural gas and hydro power which play an important role in ensuring energy security for economic development in the past two decades. Viet Nam will have great opportunities in energy transition to move forwards a low-carbon economy.

First, the Government of Viet Nam has expressed a high political commitment to the international community in achieving the net zero emissions target by 2050 through ambitious policies to reduce GHG emissions. Developing a low-carbon economy and green growth has been included in the national socio-economic development strategies and plans over the last many years. Reducing GHG emissions and increasing carbon sequestration have

become mandatory targets in socio-economic development in Vietnam. For example, Vietnam's National Energy Development Strategy to 2030, with a vision to 2045 sets a target that the proportion of renewable energy in the total primary energy supply will reach 15-20 percent by 2030; 25-30 percent by 2045. The Draft National Electricity Development Plan in the 2021-2030, with a vision to 2045 (Power Master Plan VIII) sets the orientation to gradually reduce dependence on coal-fired power and at the same time rapidly increase the share of renewable energy in electricity generation.

Second, achieving net zero emissions is an opportunity for Viet Nam to restructure its economy. Viet Nam has set a target to be a developed, high-income country by 2045. To achieve this, Viet Nam needs to accelerate its economic growth to increase per capita income and narrow down the income gap with other countries in the world. Applying advances in science, technology and innovation, implementing digital transformation, building a digital economy and digital society will be priorities of economic development in the coming period. In order to achieve net zero by 2050, Viet Nam needs to transform its economic structure towards increasing the share of industry, especially processing and manufacturing to GDP. In addition, a major recognition in the latest socio economic development strategy (2021-2030) is that the country's economic transformation will greatly depend on better management of natural capital. Like most low-income countries, Viet Nam has relied heavily on its natural resources for economic growth, using its extensive stocks of agricultural, forest, and mineral resources to drive development over the past two decades. Viet Nam will need to shift from an arguably wasteful approach to economic expansion - as producers often use more land, water, wood, energy, and other resources per unit of output than in other countries - to a development model that manages natural capital more sustainably (World Bank, 2022).

Third, aligning climate finance flows with a low-emissions and climate-resilient development roadmap is the global goal identified in the Paris Agreement. As a result, international resources (climate finance, climate-friendly technologies) to support the net zero emissions target could be increasing in the coming time. Being a country responsible for and proactive in implementing international commitments on climate change approved at COP21, Vietnam has a great opportunity to attract international support for net zero target, especially in energy transition.

However, the energy sector in Viet Nam have been facing many challenges for several reasons as follows.

First, Viet Nam is heavily dependent on fossil fuels in the total primary energy supply (TPES). Fossil fuels accounted for 74.6 percent (in 2010), 80.4 percent (in 2015) and 85 percent (in 2019) of the TPES. In terms of fossil fuel structure, coal plays an important role as the share of coal in the TPES increased from 28.1 percent (in 2010) to 40.3 percent (in 2015) and 49.1 percent (2019). Power plants consume the most coal in the country, followed by cement, fertilizer and chemical industries. The proportion of crude oil is continuously decreasing (30.7 percent in 2010 to 26 percent in 2019). The total domestic coal consumption in 2015 was about 43.8 million tons, of which power plants consumed 23.5 million tons (53.6 percent) and industry consumed 17.6 million tons (40 percent) (MOIT & DEA 2017).

The share of coal used for power generation is expected to increase from 32 percent in 2014 to 54 percent in 2030 while around 60 percent of the volume of coal used for power generation will be imported (World Bank and Ministry of Planning and Investment, 2016). In addition, the transition to fossil fuels energy is a major cause for the increase in GHG emissions in Vietnam. Over the past decade, Viet Nam recorded the highest GHG emissions in the ASEAN region. Total GHG emissions per capita in Viet Nam increased by 3 times over a 10-year period while carbon intensity per GDP increased by 48 percent (ERENA and DEA, 2019).

Second, Viet Nam witnesses a rapid growth in final energy consumption, especially oil products and electricity. The two most energy-consuming sectors in Viet Nam are industry (47 percent in 2019) and transportation (27 percent in 2019). Oil products account for the largest share of final energy consumption (34 percent in 2010 to 36 percent in 2019) (Table 2). The most notable change in the final energy consumption mix in Vietnam is the continued increase in the share of electricity consumption in the total energy consumption which reflects a shift from fossil fuel to electricity. The share of electricity consumption occupied 17 percent in 2010 and increased to 22 percent in 2015 and 29 percent in 2019 (Table 2). Vietnam's electricity system is mainly based on hydro power, accounting for 38 percent of total electricity capacity in 2019, followed by coal power (34 percent) and gas power (18 percent) (World Bank, 2018). Meanwhile, most of the hydro power potential for medium and large hydro power plants will be fully exploited and the current capacity needs to be increased further in the near future, at the same time, domestic coal is not enough to supply the coal power plants (MOIT & DEA, 2017). An important point is that the national power in the coming time will still be dependent on coal-fired thermal power, in which coal is imported which poses risks of environmental pollution and energy security.

Third, renewable energy is underdeveloped. The share of renewable energy accounts for a small proportion of the TPES in Vietnam. Renewables saw an increased share in TPES, from 11 percent in 2010 to 14.7 percent in 2015 and 16.3 percent in 2018 and fell to only 13.9 percent in 2019 despite the strong growth of solar power this year. Hydropower is the core of renewable energy in Viet Nam. The potential for hydropower development has basically been fully exploited; at the same time, small hydropower plants have caused many impacts on the environment and biodiversity. Although the development of renewable energy sources has grown tremendously in the past three years from 2018 to 2020, it also encounters problems with the transmission system and grid safety. Unsynchronized development of solar energy and power transmission system has caused waste of resources. In addition, renewable energy development has not been planned with a long-term vision and many renewable energy projects have to be supplemented and adjusted in the implementation phase, especially wind and solar energy. Some of renewable energy resources such as tidal, geothermal, biofuel, space ones have not been developed.

Fourth, Viet Nam has become an energy importer since 2015. Energy exports in Viet Nam decreased in recent years with the export volume of 12 thousand KTOE in 2015 (equivalent to 40 percent compared to 2009). Meanwhile, energy imports increased in 2015 after a few years of decline. The trend of net imports of coal, crude oil, and oil products has

turned Viet Nam into an energy import-dependent country with a net import rate of 5 percent in 2015. Viet Nam mainly imported coal and oil products. Coal imports in 2016 were of more than 10 million tons and are expected to increase in the coming years (MOIT & DEA, 2017). Although this energy import level is not high compared to other countries in the region and the rest of the world, this is a remarkable signal in the formulation of energy policy in Viet Nam in the coming time. On average, import growth was at 14.4 percent per year in 2011-2019 (Institute of Energy, 2020). The contribution of energy export is gradually decreasing which threatens energy security in the coming time.

Fifth, energy consumption is inefficiently. The national target program on efficient use of energy in the 2012-2015 set a target of saving 5-8 percent of the total energy consumption in the 2012-2015 compared to the forecasted energy demand in the National Electricity Development Plan for 2011-2020 with a vision to 2030 (equivalent to 11-17 million TOE in the period 2012-2015). MOIT & DEA (2017) showed that the actual savings was 5.65 percent, equivalent to 10,610 KTOE. The energy intensity in Viet Nam is higher than that in some countries such as Japan, Germany, Thailand, China and Korea. The energy intensity per unit of GDP in Viet Nam is twice as high as in the world.

Policy implications for a just and sustainable energy transition in Viet Nam in the coming time include: (i) facilitate rapid renewable energy deployment by improving the regulatory framework, (ii) build an attractive investment landscape for private capital, both foreign and domestic, to finance energy transition projects, (iii) improve energy system resilience by investing in the power grid's capacity and expanding energy-storage facilities for renewable energy, (iv) accelerate implementation of energy efficiency plans including effective pricing policies, (v) reform of electricity tariffs, (vi) develop natural gas to power as a transition fuel and promote consumer participation and (vii) build the local workforce required for the energy transition, paying particular attention to the livelihoods of vulnerable populations.

5.2. Conclusion

Governments around the world are currently engaged in efforts to reduce greenhouse gas emissions from fossil fuels to avert the worst effects of climate change. At the international level, countries have committed to emission reduction targets as part of the 2015 Paris Agreement on the Climate and most recently is the net zero commitment at COP 26. At national level, cities and businesses have taken up their separate commitments to reduce emissions. These efforts often focus on replacing fossil fuels with non-carbon solutions, increasing energy efficiency and using low-carbon technologies.

The energy industry is global, affecting both people and planet, and its transformation will affect all those using or producing energy - i.e. almost everybody require a just transition. Investors, insurers, energy providers and users, as well as society at large, will expect this energy transition to be conducted in a safe and sustainable way. Achieving the 2050 net zero target by accelerating the deployment of renewables and taking vigorous action to raise energy efficiency is a no-regrets strategy that meets climate objectives. It also offers the benefits of a just and inclusive energy transition, such as universal energy access, job creation, poverty reduction, and a fair sharing of adjustment benefits and burdens.

GREEN CREDIT SOLUTIONS TO MITIGATE CLIMATE CHANGE IN VIETNAM

MBA. Dang Thuy Linh

linhdt@ueh.edu.vn

Faculty of Administration, UEH University - Vinh Long Campus, Vinh Long, Vietnam

Abstract

This study focuses on providing green credit solutions as a measure to mitigate the impacts of climate change in Vietnam. The study uses a qualitative approach, with a specific focus on analyzing and evaluating policies and activities related to green credit and climate change in Vietnam. Data collection methods include analysis of policy documents, expert interviews, analysis of reports and references from relevant international organizations. The results of the study are presented in the form of an in-depth analysis and assessment of the impact of green credit policies and activities on reducing the impact of climate change in Vietnam. In addition, the study uses literature review, case study analysis and statistical analysis to provide a comprehensive understanding of green credit solutions and their effectiveness in mitigating impacts. of climate change. The study aims to contribute to ongoing efforts to promote sustainable development in Vietnam and provide insight for policymakers and financial managers on the potential of green credit solutions. in mitigating the effects of climate change.

Keywords: *Green credit, CO2 emissions, greenhouse gas emissions, climate change.*

1. Introduction

Climate change is one of the greatest challenges facing the world today, with its devastating impacts affecting all aspects of human life. Vietnam, as one of the most vulnerable countries to the impacts of climate change, has been experiencing more frequent and severe natural disasters, including floods, droughts, and storms. In recent years, the concept of "green credit" has emerged as an effective tool to promote sustainable development and mitigate the impacts of climate change. Green credit refers to financial products and services that are specifically designed to support environmentally friendly and sustainable projects.

In this context, this study focuses on providing green credit solutions as a measure to mitigate the impacts of climate change in Vietnam. Several studies have been conducted on the use of green credit in mitigating the impacts of climate change in various countries. According to a study by Rahman et al. (2022), green credit can significantly contribute to the reduction of greenhouse gas emissions and enhance the adoption of renewable energy and energy-efficient technologies. Another study by Wang et al. (2021) found that green credit policies can promote the development of sustainable transportation and support the transition towards low-carbon economy. These studies suggest that green credit can play a vital role in reducing the impact of climate change.

Green credit policies enhance environmental quality by shaping the financial sources and investments of businesses (Zhang et al., 2021b). Developing green credit improves innovation capacity and economic restructuring towards a sustainable economy (Campbell, 2021a, b; Kliestik et al., 2020; Lăzăroiu et al., 2021; Taylor, 2021) and is a tool for optimizing climate change, ecological, and energy security issues (Cui et al., 2020). Environmental finance is increasingly relevant in reducing climate change (Van Veelen, 2021). The performance of green innovation is hindered when companies face increasing financial constraints. Green finance includes climate finance but is not limited to it. It also addresses a range of other environmental targets, for example, controlling industrial pollution, sanitation, or biodiversity protection. Climate-related minimized and adaptive finance refers to investment flows into projects and programs contributing to reducing or avoiding greenhouse gas (GHG) emissions (Mohsin et al., 2019a, b), while adaptive finance refers to investments contributing to reducing the vulnerability of goods and people to the impacts of climate change. In addition, it can be harnessed for low-carbon energy, sustainable economic development, and reducing climate change during the COVID-19 pandemic (Nawaz et al., 2021). A 1% increase in the green finance index improves environmental quality by 0.375% in G7 countries, while it cleanses the environment by 0.3920% in E7 countries. Pollution reduction, switching energy sources to alternatives, innovation, and green solutions are necessary. Thus, climate change and environmental pollution reduction can be effectively achieved (Wu et al., 2021). Green finance can promote green economic growth without affecting the environment and reduce CO₂ emissions (Zhang et al., 2021). Additionally, green credit funding programs, which are also part of green finance, can improve the environment and reduce CO₂ emissions to combat climate change (Taghizadeh-Hesary & Yoshino, 2019). A study by Yoshino et al. (2021) reported that sustainable environmental goals can be achieved by using green finance and energy efficiency.

2. Method

The research method used is qualitative, focusing on analyzing and evaluating policies and activities related to green credit and climate change in Vietnam. Data collection methods include policy document analysis, expert and bank officer interviews, as well as analysis of reports and reference materials from relevant international organizations. The research results are presented in the form of in-depth analysis and evaluation of the impact of green credit policies and activities on reducing climate change in Vietnam.

Literature review method: Document research is conducted to understand policies, regulations, and green credit projects that have been implemented in Vietnam and around the world. Reference materials may include books, reports, scientific studies, policies, regulations, circulars, and laws related to green credit and climate change.

Interview method: Interviews with experts, policymakers, and financial managers on green credit policies and their role in reducing climate change. This method helps to understand in more detail the perspectives and experiences of experts and managers.

Case study method: Study of some green credit projects that have been implemented to evaluate their impact on reducing climate change. This method helps to evaluate the specific impact of green credit projects in practice.

Statistical data method: Collect and analyze statistical data related to green credit and reducing climate change in Vietnam to evaluate the impact of green credit on reducing climate change.

3. Results

In January 2020, Vietnam Prosperity Bank (VPBank) signed a green credit loan contract worth USD 212.5 million with the International Finance Corporation (IFC) and prestigious international co-sponsors. A representative of VPBank said that one-third of this financial package will be dedicated to climate-friendly projects.

By the end of 2021, the outstanding loans for green projects reached over VND 441 trillion (accounting for 4.2% of the total outstanding loans of the entire economy), an increase of 32.5% compared to 2020. Notably, the outstanding credit for renewable energy projects reached more than VND 212 trillion, accounting for about 47% of the green credit balance of the entire system.

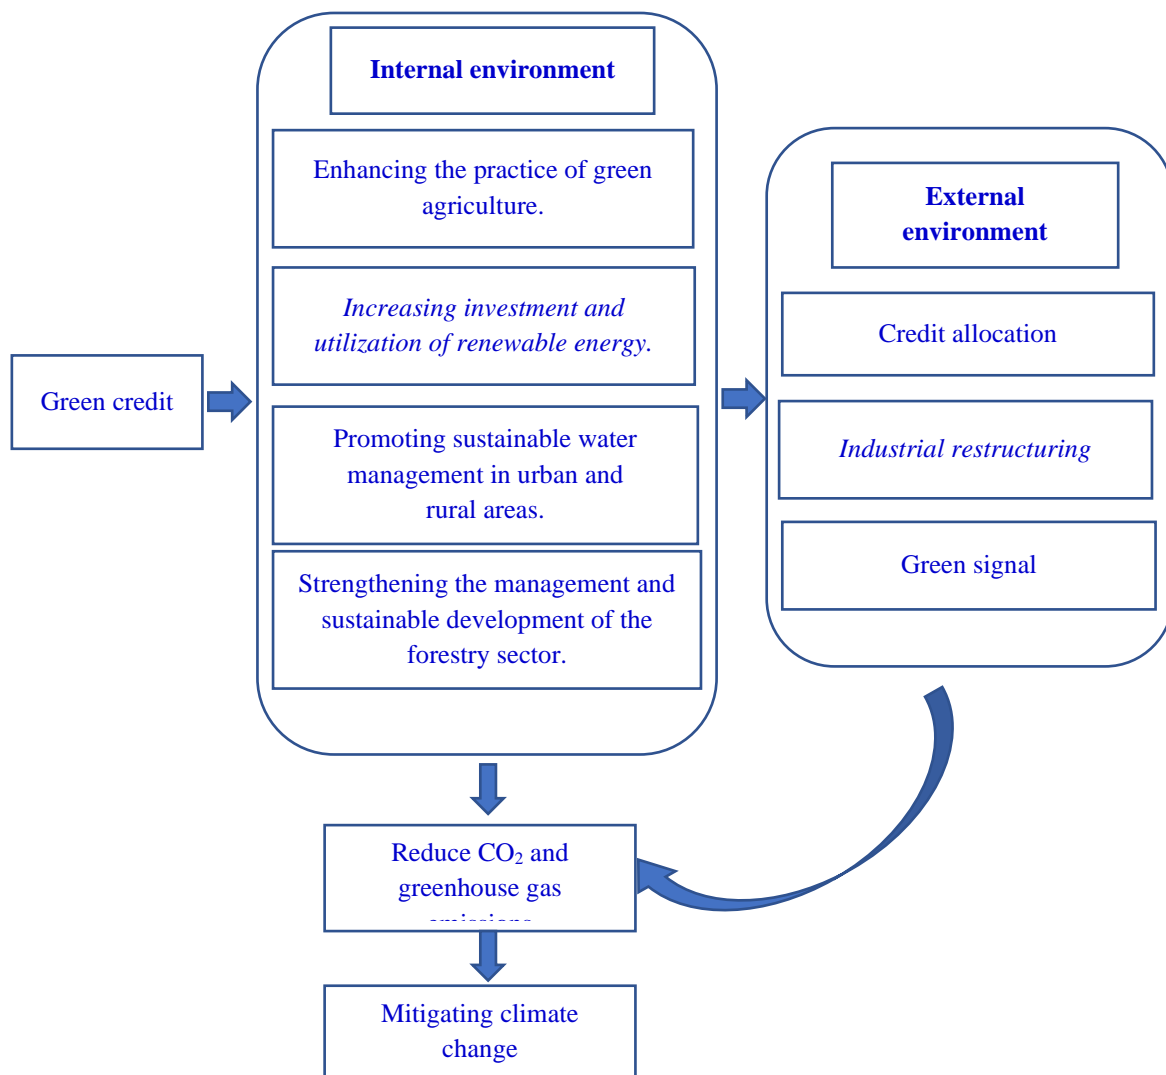

Figure 1. The mechanism of how green credit impacts the reduction of CO₂ emissions to mitigate climate change

In 2020, the agriculture sector was the second largest contributor to Vietnam's greenhouse gas emissions, accounting for approximately 19% of the total emissions. Rice production accounted for about 48% of these emissions, followed by livestock manure fermentation (15.3%), synthetic fertilizer use (12.9%), and manure management (9.5%).

To reduce greenhouse gas emissions, the implementation of green agriculture, the following measures will be taken: (i) Reduce greenhouse gas emissions in agricultural production by reducing the use of fertilizers and pesticides by 14%. (ii) Change animal feed, animal health, and breeding methods to reduce greenhouse gas emissions by 14% per animal unit. (iii) Increase forest service subsidies by 50% (compared to BAU) to encourage reforestation and increase carbon sinks. These measures will require significant new investments from both the private and public sectors, estimated at around \$15.6 billion from 2022 to 2040.

Table 1. Outstanding green credit packages of commercial banks in green agriculture

Bank	Outstanding green credit package
Agribank, Vietinbank, Vietcombank, HDBank, ACB, BacAbank, Sacombank	The State Bank of Vietnam issued Resolution 813 / QD - SBV on July 24, 2017 to direct commercial banks to implement a loan program to promote the development of high-tech agriculture. Following the State Bank's guidance, a VND 135 trillion loan package for high-tech agriculture was launched by eight established banks. In which Agribank's total investment in the loan package is VND 50 trillion, while Vietinbank, Vietcombank, and HDBank each committed to providing VND 10 trillion. Bac A, Sacombank, ACB, and others recorded a total of VND 55 trillion.
Agribank	Reduced interest rates for loans from 0.5% to 15% per annum for customers participating in the clean agricultural production chain, depending on the time when customers participate in different stages of the high-tech agricultural production process: supplying input materials, production or product consumption. Customers borrowing under the High-tech Agriculture Development Program, clean agriculture are free of charge for transfer within the Agribank system and receive a 50% reduction in transfer fees outside the Agribank system.
HDBank	Implement the program of high-tech agricultural loans with a limit of VND 10,000 billion at the request of the Government and the State Bank. Specifically, in this program HDBank applies an interest rate lower by 1% than the normal interest rate. Loan limit can reach 80% and businesses can mortgage assets formed from loan capital. The maximum loan term is 10 years. The bank has implemented a number of affiliate programs with supermarket chains and convenience stores across the country and built an export program with professional financial solutions to make it easier for businesses to providing clean agricultural products to consumers.

According to the national strategy on clean water supply and rural sanitation until 2020 approved by the Prime Minister in Decision No. 104/2000/QD-TTg on August 25, 2000, after

20 years of implementation with initiatives, efforts of the government and support of international organizations, significant and fundamental progress has been made. Regarding clean water supply, by 2020, 88.5% of the rural population had access to clean and hygienic water (nearly 51% of which met the Ministry of Health's standards). Regarding sanitation, by the end of 2019, 75% of households had hygienic latrines. Furthermore, the provision of clean water in rural areas is increasing, and the state management system is being improved.

Table 2. Outstanding green credit packages of commercial banks in the field of clean water

Bank	Outstanding green credit package
ADB	A loan of USD 45 million for Clean Water Supply and Environmental Treatment Project in Rural Central Region
Agribank	Participating in the project of rural clean water supply and sanitation in the Red River Delta sponsored by the World Bank (WB)

Sustainable forest management for the 2016-2020 period was established as a target program through Resolution No. 886/QĐ-TTg on June 16, 2017 by the Prime Minister. Agribank has been designated as a support bank for the Forest Sector Modernization and Coastal Resilience (FMCR) project. The FMCR project aims to improve coastal forest management to better withstand adverse weather conditions and sea level rise, protect the ecological environment and effectively respond to climate change. At the same time, expand and improve the value chain of forest products, improve people's livelihood, participate in the protection and development of coastal forests. In 2016, the Government approved the adjusted National Power Development Master Plan (PDP 7) for the period 2011-2020 with a vision to 2030. The main objective is to increase the share of renewable energy, not including hydropower, to more than 10% by 2030. The plan aims to further reduce the country's dependence on hydropower over the next few years, from about 40% in 2018 to 15% by 2030.

Figure 2. Target for electricity generation from renewable sources in revised PDP-7

Source: Industry and Trade Magazine, 2022

Electricity of Vietnam (EVN) estimates that about USD 150 billion will be needed by 2030 to meet the increasing demand for electricity. The financial requirement for the

renewable energy sector is about USD 24 billion by 2030. Therefore, Vietnam needs to attract about USD 10 billion in investment by 2030 to meet the growing demand of the country. For this reason, more and more investors are interested in developing renewable energy projects. Many banks have also started offering credit packages with great value to facilitate the development of this green energy industry. (Table 3)

Table 3. Some outstanding green credit packages of commercial banks in the field of renewable energy

Bank	Outstanding green credit package
BIDV	Up to 75% of the total investment capital of a rooftop solar power system with an interest rate of 10% per year for a period of 12 to 36 months, coordinated by Bach Khoa Solar Energy Development and Investment Joint Stock Company with banks to support participating households. The bank has granted credit to many large-scale wind power projects such as Huong Linh 1 and Huong Linh 2 (Quang Tri, total capacity of 60MW) and Phuong Mai 3 project (Binh Dinh) with a capacity of 20.7 MW.
Sacombank	Credit program up to 70% of investment capital in solar energy projects for corporate customers in the Southwest, Southeast, South Central and Central Highlands regions. Preferential interest rate of 8.5%/year for the first year, maximum loan term of 96 months. We offer a loan package of up to VND 500 million with an interest rate reduced by 1% compared to the current interest rate. The loan term is up to 60 months, applicable to individual customers who need to buy a solar power system every day to serve their daily living and business needs.
TPBank	The bank has financed VND 11,000 billion within 2 years for Bamboo Capital Group (BCG) with renewable energy projects with a total capacity of 1.5GW. It is used for wind power projects with a total capacity of 650 MW in Ca Mau, Vung Tau, Soc Trang and Tra Vinh provinces. Rooftop solar power projects and 330MW solar power plants in Binh Dinh.
Vietcombank	The bank provides loans for 3 projects: Srepok 1, Srepok 2, and BP Solar. Srepok 1 has a total investment of about VND 1,200 billion in Dak Lak. Srepok 2 and BP Solar 1 are two projects in Phuoc Huu, Ninh Thuan. In addition, Vietcombank has provided a loan of VND 360 billion to implement the Ban Ang hydroelectric plant project in Nghe An.
HDBank	As of 2018, the bank has spent VND 7 trillion on clean energy and renewable energy projects and VND 3 trillion on disposable power projects. Specifically, the bank has provided financing to companies investing in rooftop solar projects. The loan interest rate is up to 70%, with a loan term of 5 years.
NamABank	NamABank has signed an agreement with the Global Climate Cooperation Fund to implement the Green Credit Program in Vietnam. Accordingly, the bank will grant medium and long-term green credits for projects that reduce carbon dioxide emissions and projects that save 20% of energy demand.

Bank	Outstanding green credit package
MB	The bank has provided capital for 34 solar and wind power projects with a total value of about VND 70,000 billion, helping investors generate about 3,600 MW of renewable energy and contributing to the increase in clean energy sources. while promoting the economy to meet the needs of sustainable growth.

Vietnam is currently ranked in the top 10 countries with the largest investment in renewable energy (RE) in the world in 2022, with USD 7.4 billion, surpassing two major economies of Germany and France.

Vietnam is vulnerable to climate change, it ranks fifth in climate risk in the Global Climate Risk Index 2018 and eighth in the Long-Term Climate Risk Index (CRI), a list of 10 countries most affected by extreme weather events from 1997 to 2016 (on average per year).

(Unit: VND billion)

Figure 3. Financial needs for the implementation of the Target Program to Respond to CC and Green Growth for the period of 2016-2020

Source: Resolution No. 73/NQ-CP on August 26th, 2016

Intended Nationally Determined Contributions (INDCs) were approved by the Prime Minister in 2015 and submitted to the Secretariat of the United Nations Framework Convention on Climate Change (UNFCCC). Vietnam's INDC includes contributions to greenhouse gas emissions mitigation and adaptation to climate change, including both unconditional and conditional contributions (can be made if Vietnam financial and technology support and capacity building from international organizations). According to estimates in Vietnam's INDC, the total domestic financial need to achieve the targets. The 8% cost of GHG emission reduction is USD 3.2 billion and Vietnam needs an additional USD 17.9 billion. from international support to achieve 25% GHG emission reductions under the development-as-usual scenarios. The total

financial need to achieve the target of reducing greenhouse gas emissions for the period 2021-2030 is as follows:

Table 4. Total financial requirements to achieve GHG emission reduction target 2021-2030

Field	Method	Reduction target by 2030	Expense (millions of dollars)
Energy	Self-implemented	4.4	1,894.3
	Supported	9.8	5,332.8
Agriculture	Self-implemented	5.8	885.43
	Supported	41.8	12,093.54
Waste	Self-implemented	8.6	311.7
	Supported	42.1	2,596.2
Land use, land-use change and forestry (LULUCF)*	Self-implemented	50.05*	131.98
	Supported	145.7*	1,127.98
Domestic cost			3,223.41
Additional support			17,927.11
Total cost			21,150.52

Source: INDCs of Vietnam, 2015

* Note: Increase the ability to absorb greenhouse gas.

Financing for climate change adaptation and green growth in Vietnam can be mobilized from a variety of sources such as state budget capital, international funding (ODA, preferential commercial loans), incentives from major international financial institutions and capital from international climate funds) and domestic private capital (loans from credit institutions, own capital). However, state budget capital and ODA only meet about 10% of the capital demand for green growth. The rest of the capital is raised from the private sector. Currently, the capital market of Vietnam has not really developed, the financial source for businesses is still mainly based on bank loans. Therefore, Vietnam's banking system has played a particularly important role in maintaining economic growth and thereby affecting the environment and social community. As such, it will become the main source of capital for green industries.

4. Discussion and Conclusion

Green credit solutions to mitigate climate change in Vietnam:

- Firstly, the government can enhance policies to encourage and support banks and financial organizations to participate in green funding projects. This can promote green funding activities for urban projects, public transportation, renewable energy development, and sustainable agriculture to reduce carbon emissions, increase climate resilience, and protect the environment. Banks and financial organizations may receive tax incentives or financial support for investing in green funding projects, such as interest rate support, tax reductions, or increased access to capital.

- Secondly, policies should be put in place to encourage and support banks and financial organizations to apply green standards in the evaluation process of funding projects. This ensures that projects are developed and implemented according to environmental protection standards, creating quality green funding projects and reducing climate change. Applying green standards helps banks and financial organizations assess the risks and renewability potential of funding projects. This will enhance the sustainability of projects and reduce negative impacts on the environment and climate change. At the same time, applying green standards also helps increase investor and customer confidence in green funding projects, attracting new investments into green funding projects.

- Thirdly, creating new green financial products is necessary. Financial institutions and banks can encourage investors to invest in research and development of new green financial products. This will help create new financial products that meet the requirements of green funding projects and increase capital mobilization for green funding projects. One of the best ways to enhance capital mobilization for green funding projects is to create green investment funds. These funds can be invested in industries such as renewable energy, ecological agriculture, and green urban projects.

- Fourthly, green credit institutions can play a crucial role in raising awareness and knowledge among individuals, businesses, and communities about the importance of green finance and its potential in mitigating climate change. This can be achieved through educational campaigns, workshops, and training programs.

- Fifthly, green credit can support research and development efforts aimed at innovating and implementing energy-saving technologies. This includes funding projects focused on energy storage, smart grids, and sustainable transportation, which contribute to reducing greenhouse gas emissions.

- Finally, financial institutions can issue green credits specifically designated for environmentally friendly projects. These credits provide favorable terms and conditions, such as lower interest rates, longer repayment periods, and flexible collateral requirements, incentivizing businesses and individuals to undertake sustainable initiatives.

Conclusion

In the context of climate change causing significant impacts on Vietnam, green credit solutions have been proposed as an effective approach to mitigate climate change and ensure sustainable development. By generating financial products and services that support green projects and activities, green credit plays a crucial role in promoting the transition to a green economy and reducing emissions. The mentioned green credit solutions, such as financial support for renewable energy projects, energy-efficient housing construction, training and raising awareness about green finance, investment in research and development of energy-saving technologies, and the issuance of green credits, contribute significantly to reducing

climate change in Vietnam. However, for green credit to be truly effective in reducing climate change, close coordination among stakeholders is necessary, including the government, banks, businesses, and the community. Consensus and policy support are needed to encourage the development of green finance and ensure the efficient and sustainable implementation of green projects. In the future, the development of green credit in Vietnam needs to be continued and expanded. Additionally, other financial measures such as tax incentives and investment promotion should be implemented to create a favorable environment for the development of green projects and activities. Only through these efforts can Vietnam achieve its goals of minimizing climate change and protecting the environment in a sustainable manner.

ENVIRONMENTAL COMMUNICATION THROUGH THE CASE STUDY OF PLASTIC WASTE COMMUNICATION PRODUCTS IN VIETNAM

Assoc. Prof. Dr. Dinh Kieu Chau

dinhkieuchau2020@gmail.com

*University of Social Sciences and Humanities,
National University, Hanoi, Vietnam*

Abstract

This case study discusses the topic of communication products in the field of behavior change communication with plastic waste in Vietnam. The research is carried out in the direction of combining qualitative and quantitative methods, focusing on the description and analysis of selected media products in terms of their ability to reach the target audience. The research results show that the media product design has the actual following advantages: modern and relevant in terms of information, valuable impact as well as meaningful in terms of interpersonal relationships. However, the products still have limitations related to communication interference as well as information selection and organization. Based on the survey, we have tried to provide solutional discussions in community development communication practices in Vietnam.

Keywords: *communication products, behavior change, strategy, approach, target audience.*

1. Introduction

In social aspect, communication is a powerful communication tool of influence and conquest. Thanks to this powerful feature, the media is increasingly asserting its role and position in the service of sustainable development goals for the community.

The environment is one of the areas of community development that is always deeply concerned with the global scale due to its influence on human life. Environmental issues involve many levels from macro to micro and are often solved in an integrated way to achieve lasting change effect. In fact, environmental communication has played a very important role in this process due to its large capacity to mobilize social resources and its results can be covered on a large scale. This is considered a practical support solution in environmental governance, and at the same time a channel to help bring environmental policies into social life.

In the communication process, the construction of communication products is an important step. If this is done professionally, the communication will be easier to reach the audience and easier to achieve.

With that in mind, we have conducted a case study on environmental communication products related to efforts to reduce plastic waste, a current topical issue in Vietnam.

Through this study, from a social media perspective, we want to identify some practical media product design features, on that basis, try to give solutions-based discussions in community development communication in Vietnam.

2. Theoretical basis

From a media perspective

Based on some research we have done, we would like to introduce the concept of communication as the basis for this survey as follows: Communication is a continuous process of exchanging and sharing information, creating mutual links. to lead to understanding, change in perception and behavior of the target audience in a voluntary, gradual and sustainable manner.

Communication works based on the mechanism of basic principles: cooperation, orientation and art with a closed process including many factors: source, destination, message, channel, feedback and noise. These factors need to be seen in a close systematic relationship and placed in the specific communication context. (James Watson & Anne Hill, 1993)

In the process of communication, the message is both the medium and the result of the source, so it has a very important position. All information and desires oriented from the source are through the message to the destination. In fact, messages always exist as specific communication products and need to follow marketing principles in design (both in terms of content and form) in order to have the best reach with the target object. The quality of communication products should be based on the basic principles of communication.

Communication is a very broad field with many branches, one of which is related to social marketing, serving the needs of community development, which is behavior change communication (TCM) associated with the term IEC: Information (information - content), Education (education - goal), Communication (communication/communication - method). This is a combination of three aspects in a particular type of information activity aimed at influencing the object with the desire to intervene to create changes in the object. In this case, communication is considered as a purposeful, planned activity aimed at achieving a change in the knowledge, attitudes, and skills of the audience, helping the audience to accept and sustain new behaviour. (Thanh Xuan Nghien, Hoang Kim Thanh, Trinh Son, 2003)

In all communication activities, the media product is used as a strategic impact tool. Through specific communication products, the source influences the target audience during their approach, changing the direction and desire of the source.

Behavior change is a long-term process consisting of many stages, complex in the psychology of action of the target audience, so it is not easy to succeed.

This requires having a communication strategy suitable for each stage of the behavior change process as well as for each individual target group, while also paying attention to the characteristics of the society. Thus, the design of communication products for the purpose of behavior change must also fall within this strategic direction.

Figure 1. Transtheoretical Model of Change

Source: <https://www.masterskills.org/Training-models-Change-Phases.htm>

From a practical perspective

Plastic waste is currently an environmental hot spot in Vietnam. The article titled "Vietnam discharges 3.1 million tons of plastic waste into the environment every year" on Vnexpress (the most widely read online newspaper today) has cited figures from the report of the Bank. World Bank announced on July 25, 2022. It is on land that each year an estimated 3.1 million tons of plastic waste is generated and the amount of waste dumped into the ocean is between 0.28 and 0.73 million tons. At the same time, this report also shows that by 2030, less than 15 years from now, the amount of waste generated in Vietnam is expected to double from 27 million to 54 million tons.

According to another statistics of the Vietnam Plastics Association, the amount of plastic waste and plastic bags in Vietnam accounts for about 8% to 12% of domestic solid waste, but only about 11% to 12% of the waste. Plastic, plastic bags are treated and recycled, the rest is mainly buried, burned and discharged into the environment. Although the area of Vietnam ranks 68th in the world, it ranks 4th in the world in terms of plastic waste, with more than 1.85 million tons/year. This has made pollution in Vietnam more serious, because plastic waste affects the landscape, living environment, human health and species, causing damage to economic sectors such as: tourism, or fishing, aquaculture, seafood.

Faced with that fact, Vietnam has made many efforts towards the goal of reducing plastic waste. Behavior change communication has played an important role throughout this process. The most significant recent move is on May 2, 2021, the Prime Minister issued Decision No: 175/QĐ-TTg on promoting propaganda to prevent plastic waste in the period of 2021 - 2025 with the following objectives and very specific implementation. Up to now,

many communication products on reducing plastic waste have been created and put into practice. The sources of these products are also very diverse (Government agencies, organizations, social organizations...) with different levels (from central to local, even spontaneous small groups).

3. Method

As a basis for research, we randomly selected 70 tabular communication products (posters, banners, infographics) with content related to reducing plastic waste as research samples. This is a modern communication product, concise in terms of information, with high flexibility and applicability in many types of space, convenient in contact with Vietnamese people because there is a culture of receiving ancient paintings. previous action.

Samples are collected from a variety of use spaces (outdoors, indoor, online media), diverse in terms of creative sources and time of appearance.

The research is carried out in the direction of combining qualitative and quantitative focusing on the description and analysis of selected media products in terms of their ability to reach the target audience.

4. Results

In terms of information content of media products

Through specific surveys, we find that communication information in products is a combination of visual symbols and language and is classified into two main categories.

Intellectual information: this is the type of information that occupies a large amount and plays a dominant role in content in communication products (about 88%). This information focuses on the purpose of providing knowledge, improving understanding and calling and guiding action for the target audience (Table 1).

Table 1. Research results of Intellectual information

No.	Information Type	Content	Characteristics	Proportion
1	Basic Concept	- What is plastic waste? - Source of plastic waste - Lifetime of plastic waste	Explanation Presentation	8 %
2	Current Situation	Providing data: - Volume of plastic waste discharged - The scale of environmental space is affected - Efforts to reduce plastic waste have been made in the world and in Vietnam	Description	15.5%

No.	Information Type	Content	Characteristics	Proportion
3	Reasons to Change	Emphasizing the serious and long-term effects of plastic waste on people and the environment	Explanation Presentation	10%
4	Action Guide	Introducing how to choose, use alternative materials to change and replace.	Description	49%
5	Call to Action	Persuading and promoting new behavior	Encouragement	17.5%

Source: author analysis (2022)

Some examples:

Emotional information: This type of information is intended to affect the receiving psychology of the target group by seeking sympathy for the plastic waste problem based on the impact of sharing or evoking sympathy of the recipient information before a certain fact. In addition, emotional information also emphasizes the aspect of enhancing the role of the receiver or transferring the choice to the receiver through suggestions. Emotional information only accounts for about 12% of all survey products

Some examples

In terms of organizational structure of media products

Although the communication products in this study are single-media, only acting through the visual channel, there are a variety of combinations of signs and expressions: language, drawings, and photographs. The information is presented on a limited spatial scale and is not linear.

About the amount of information: because the product is a compressed form of information, many products are designed to be neat and concise such as: in terms of language, priority is given to the use of words and phrases that rarely appear in the form of sentences or linked text. Regarding images, there is a preference for images with realistic visualization, less use of image metaphors.

About product texture: We see a certain variety

* Integrated information: these are products with a combination of many types of information on one product space in which the following structures are prominent:

- a. Action Guide + Call to Action.
- b. Current Status + Action Guide
- c. Status + Call to Action
- d. Harm + Call to Action

With integrated information, the focal point of the information is related to the prominent sizes and colors of important details.

* Unique information: these are products that do not have a combination of multiple types of information on one product space. Appearing in this product category are all types of information classified above: basic concept, situation, rationale, action guide and call

With this type of organization, the type of Guide to Action and Call to Action makes up the majority

In terms of strategic approach of media products

To reach the target audience, the media products surveyed by this study followed the following strategies:

* Transparency: keywords and images related to the content to be communicated are presented directly, clearly, without ambiguity, without misleading

Key points are repeated over and over again in many different products. Here are the most frequently used words/phrases:

- Plastic waste: content to be communicated
- Mitigation: the goal to be achieved of the communication
- How: guide behavior change
- Action: promote behavior change
- Say no: advocate for behavior change

* Friendly: In the survey products, the highlight of the communication strategy is to attach importance to the position of the target, limit the imposition and abuse of the source's communication power.

The results show that there are almost no speech acts with high pressure showing controlling power such as commanding and requesting, but instead verbal acts showing power interaction such as: provide information, advice, explain, encourage, demonstrate, present, suggest, dissuade, warn...

5. Discussion and conclusion

In terms of product advantages, the survey shows that many communication products have been designed in the direction of modernization and professionalization, so it is convenient to reach the target community on a large scale. This is reflected in the following aspects:

- Rich, systematic and coherent in terms of content as well as form of information presentation
- Up-to-date and focused information content needs to be communicated
- There has been a certain link between the information conveyed and the specific goals of each stage in the entire behavior change process.

- Information is easy to understand and remember because it is presented in a concise, clear and specific way (for example, there are no terms, technical words, local words, etc.) and is repeated in meaningful content.

- Shows the orientation of the source, but limits the imposition but instead enhances the role and voluntariness of the target (ensures the basic characteristics of the communication)

In terms of access to media products in the survey, to some extent, informational relevance, impact value and interpersonal significance.

About product limitations

The most significant limitations of media products relate to some of the following:

* Communication interference

Media products are the result of an artistic creative process. However, it is easy to see that there is a boring, clichéd repetition of expressions in many products

For example, the slogan "Say no to plastic waste" appeared repeatedly in many surveyed products. Not to mention the phrase "Say no to..." has been used in many different communication programs, so in this case it can lose the creativity of the design.

On the other hand, due to the heavy emphasis on the amount of information transmitted, many products are overloaded with information in a limited space. This is most evident in the type of integrated information products, making it very difficult for the target to recognize or accurately remember key information.

* Information gaps

In the products that have shown the richness of information content, the communication strategy still has shortcomings in establishing information focus.

In fact, in order to change the target's behavior, the benefit factor of the target is very important. They only really care and change if they see the right reasons, the need for change as well as the benefits that they enjoy. According to the survey results presented in Table 1, the information on the reasons for change is very limited (only about 10%). Media products are emphasizing impact through numbers and guidance. However, information about the harmful effects of plastic waste, especially the direct harm to human health (safety needs) is the key to open the door to change before focusing on practical guidelines, persuasive actions or movements.

On the other hand, the active role of the target is not fully understood. Media products still pay little attention to interventions through improving the image of the target, especially with the group of people who use plastic products, such as promoting the target in an effort to change to have a new behavior (becoming a trendy person, a more responsible person, a more knowledgeable person...)

In addition, there is information that is not factual. For example, the campaign slogan "say no" to plastic waste. In this case, the listener finds himself or herself being put to fulfill an idealized request that is difficult to fulfill, leading to an easy psychology of giving up. Instead, emphasis should be placed on whether "restriction" or "alternative" are more viable suggestions.

* There is no clear target classification yet

Plastic waste is a topical content when communicating, but related to this content, there are many specific target groups (objects of mind) such as: producers, users, people. This requires product designs to have a categorical orientation in their approach. The work results show that the survey media product has not paid adequate attention to this issue. Messages, especially for Hazards and Action Instructions, are a must-have, but most products are designed in a generic way, without any sign (language) markings, language, images) to differentiate in reaching the target group.

* Few traces of indigenous culture

The survey shows that many products have modern designs and gradually approach internationalization. This can help quickly capture the target's attention at first. However, in

order to transform information from short-term memory to long-term memory or recall, familiar indigenous cultural factors play an important role. In fact, current designs have not focused on this content. (During the survey, we only encountered one product that used folk elements as folk songs to create slogans).

Some suggestions for behavior change communication product design

Behavior change communication is an informational process that is both educational and instructive based on deep understanding of the object of intervention, in which new behavior always occurs under certain influences. The educational structure of behavioral change intervention in mass communication communication can be visualized as the following formula:

Behavior = Perception + Attitude + Belief + Practice

(Thành Xuân Nghiê, Hoàng Kim Thanh, Trịnh Sơn, 2003)

Achieving the result that the subject changes and sustains the new behavior as desired by the source requires the media to apply many skills and methods in practice. For media products, the designs should be based on the integrated approach of Mass Communication and Social Marketing, persuading according to the principle of "long rain, gradually permeating", compatible with the target audience's level, lifestyle, culture, and ability to perform, namely:

Appropriate: Information will be accepted if it is consistent with the attitudes, beliefs, practices, values and interests of the target audience. Furthermore, this fit needs to be flexible for each stage of the entire behavior change process.

Selective exposure: the target of communication is not as active as the source, but not completely passive. They will reject information that is considered illogical, too strange or psychologically pressurized...

+ Perceiving and remembering selectively: In the information chain, listeners usually only pay attention and choose the focal points of information:

- * Relating to the needs and desires of the object.
- * Compatible with the audience's level and culture
- * Close to the interests of the object
- * Help strengthen or build the trust of the subject

+ Ability to categorize: the target audience of the communication includes many individuals, is not uniform in perception, psychology, etc., so the communication information must also be specific and oriented to the acceptance of the majority. It is necessary to take into account the personality of the recipient (thinking capacity, belief, authority, and cultural depth).

Mass media communication is generally public relations with both universality and specificity. This is a combination of "international" and "localization" characteristics associated with local thinking and culture. Thus, in order to design effectively, communicators also need to pay attention to the following skills:

- Information-seeking skills help designers understand the needs, desires, and deficiencies that need to be compensated for by each target group (target approach). This is the basis for deciding the attitude and behavior of the listener.

- Observation skills help designers understand the actual situation, determine the status, the level of need for intervention, and choose the appropriate solution in the products (access the status quo).

- Communication skills. Message designers always have to show creativity and personality in finding ways to convey the message content so that the recipient can receive it in the best and most convenient way.

- Listening skills. This belongs to the feedback in the media. When the message is broadcast, there will be a response from the public. Due to different interests, different interests, responses are also diverse. However, designers must aim for common interests, share and understand public aspirations when redesigning products.

It can be seen that TDVH communication product is a new type of product that is typical for modern community communication in Vietnam. This type of message is being socialized and developed rapidly, applying modern design theories and techniques associated with many social programs. However, this also poses new research requirements both in terms of theory and practice to improve product quality in a more professional and effective manner.

DEVELOPING GREEN BANKS IN THE CONTEXT OF DIGITAL TRANSFORMATION IN VIETNAM COMMERCIAL BANKS TODAY

MA. Vu Thanh Tung

vt.tung@ufm.edu.vn

Faculty of Finance and Banking,

University of Finance and Marketing, HoChiMinh city, Vietnam

Abstract

Digital transformation has developed strongly in the world today. For many years, our banking system has always played an important role in Vietnam economy, so the application of digital transformation in banking activities is an inevitable trend. Vietnam State Bank of Vietnam trends to promote the whole system to follow the modern trend of linking digital transformation with green development. Recognizing the importance of the issue, this paper presents some general theoretical basis of green banking and digital transformation, assessing and analyzing the current situation of green banking development in the context of digital transformation, thereby proposing some practical solutions applied to banking operations.

Key words: *digital transformation, digital transformation of Vietnam banks, green economy, green banks, Vietnam banking.*

1. Introduction

Nowadays environmental preservation and sustainable development are widely acknowledged all over the world. Organizations, including State agencies and sole proprietorship are worried about the overall effect of depletion of the surroundings and pollution on business activities. Governments, businesses and individuals have all contributed their owns to prevent global warming and creating a more sustainable world, which need long-term plans and visions. Financial institutions, especially banks, are also playing a key role in improving that process, as well as assisting in the development of a robust and successful low-carbon economics.

Green banks are mission-driven financial firms to speed the transition to sustainable energy and combat climate change. Green banks are more enduring and capable of developing organizational culture and competence. They rely on loans rather than subsidies. They would like to promote banks to invest in sustainable, low-carbon businesses that produce long-term profitability. Modern green banks trend to care more about installing renewable energy than making profits. Their investment products can be electric automobiles, smart power networks, and renewable energy systems...They stop financing damaging sectors like fossil fuels. They should make more uses of environmental data when extending credit and making investment decisions. The focus of Green Banking is to combat climate change. Generally, green banking system may help government save, invest, and contribute to protect the environment.

Some research papers have recently studied green banking practices, their methods of adoption and importance of practicing green banking, also including the role and contribution of banks in environmental sustainability. This paper examines and represents these issues in some typical Vietnam commercial banks today.

2. Theoretical Basis

The green economy

The concept of the Green Economy has been founded since the early second half of the twentieth century, first addressed in a UK government sustainability report in 1989. By 2012, it was internationally agreed upon to use at the United Nations Summit on Sustainable Development held in June 2012 in Rio de Janeiro, Brazil. Since then, the green economy has gradually become a popular global concept. In Vietnam, it first appeared in 2010.

The United Nations Environment Programme (UNEP) (2012) defined the Green Economy as "one that results in improved human well-being and social equity, while significantly reducing environmental risks and ecological scarcities." In its simplest expression, a Green Economy can be considered as one that is low in carbon, resource efficient and socially inclusive.

According to the European Union (EU (2012), the green economy is a smart, sustainable and fairly growth economy

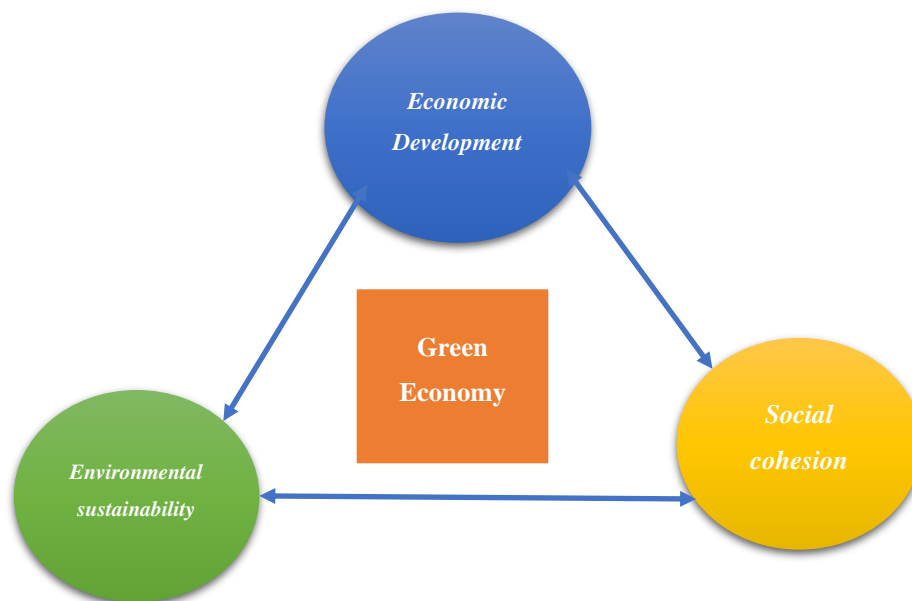

Figure 1. Three pillars of the green economy

Source: The Author collected (2023)

Green growth

The United Nations Economic and Social Commission for Asia and the Pacific (UNESCAP) (2012) defined green growth as a strategy that seeks to maximize economic output and minimize ecological burden; a new approach that seeks harmony between

economic growth and environmental sustainability by promoting fundamental changes in social production and consumption.

According to UNEP statistics (2016), over the past 25 years, the world economy has grown four times higher than the past. But economic development has been largely based on resource extraction without paying attention to renewables, leading to serious ecosystem damage. As a result, 60% of the goods and services produced have negatively affected our planet’s ecosystem. To fix this situation, protecting the living environment is just to secure human life. Global countries have focused on a new growth model - *the Green Economy model (green growth)*.

Green banking

Green banking is an inevitable trend of developing the national banking system in the green growth strategy. Kaeufer (2010) and González (2008) pointed out the inevitable trend of developing a green banking model with the provision of financial services, which affected a lot on banking efficiency, environmental protection, ensuring green and sustainable growth. Green banking is divided into 5 levels of development, from low to high:

Figure 2. The green banking model with 5 levels

Source: Kaeufer (2010)

In opinions of Imeson M., and Sim A. (2010), green banks were simply sustainable banks. According to UNESCAP (2012), green banking referred to activities that encourage environmental activities and reduce carbon emissions; they promoted the use of green products and services and applied environmental standards to approve loans or provide preferential credits for CO2 reduction projects.

According to Kanak Tara and Ritesh Kumar (2015), green banking was understood as ways of providing banking services which support operations having positive impacts on the environment, reducing carbon emissions, saving natural resources, and promoting sustainable development.

In SOGESID's ideas (2012), a green bank could operate like a traditional bank, while implementing programs that benefit communities and environment; it was a combination which ensures harmony and sustainability in economy - environment - society.

Digital transformation of the banking industry

Microsoft (2017) defined digital transformation as restructuring thinking in the coordination among data, processes and people to create new values.

In Vietnam, Minister of Information and Communications, mr Nguyen Manh Hung (2021) emphasized, "Digital transformation is not a revolution of technology but an institutional revolution. Institutions need to improve in advance and flexibly adapt to accept new things: new technologies, new products, new services, new models."

According to FsiVietnam (2021), digital transformation in banking was the integration of digitalization and digital technology into all banking sectors; this integration enabled the creation or modification for existing business processes, cultures and customer experiences to meet market requirements and customer desires; digital transformation helped banks save costs and rationalize operational processes; this integration also makes the customer experience easier and more attractive.

3. Method

Based on the theoretical basis presented on green banking and digital transformation in the banking industry, this paper collect secondary data, using qualitative research methods to assess and analyze the current situation of green banking development in Vietnam commercial banking system today in the context that digital transformation is becoming a major trend in the world and Vietnam, which is strongly supported and encouraged by our Government. On the basis of recognizing the advantages and disadvantages, the author proposes some solutions to effectively solve the remaining problems in reality.

4. Results

4.1. General policy

Like many developing countries in the world, Vietnam is facing the challenge of ensuring both economic growth and development of a sustainable green economy. In recent years, despite important achievements in economic development and poverty reduction, the quality of development has not been sustainable, resources have been wasted and seriously lost, and the environment and ecosystem have been increasingly being polluted. To solve this reality, the Government of Vietnam has made efforts to change the growth model, restructuring our economy towards sustainable development, improving the impact of climate change, and linking the economy with green growth. The Green growth strategy for the period 2011-2020 and vision to 2050 issued by the Government defined these following main tasks:

- Greening production: Restructuring the economy towards shifting from broad-based to in-depth development, reducing the use of natural resources, strengthening ecological industries and environmental services, innovating technology, and using advanced and environmentally friendly technologies.

- Reducing greenhouse gas emission intensity per gross domestic product growth and increasing the use of renewable energy use.

- Greening lifestyles and sustainable consumption: Greening production cannot be done without the sustainable lifestyle and consumption in society.

In Vietnam, the issue of green banking has been mentioned since 2011. According to Decision 1393/QĐ-TTg dated 25/9/2012 of the Prime Minister approving the national strategy on green growth for the period 2011-2020 and vision to 2050, "Green Finance" and "Green Banking" were considered parts of the "Green Growth". Based on Decision 403/QĐ-TTg dated 20/03/2014 of the Prime Minister approving the National Action Plan on Green Growth for the period 2014-2020, on 06/08/2015, the Governor of the State Bank issued Decision No. 1552/QĐ-NHNN for the Action Plan of the banking sector to implement the National Green Growth Strategy to 2020. Accordingly, the objective of the Action Plan of the banking sector is to effectively implement the National Green Growth Strategy, contributing to promote the green growth process for a low-carbon economy, reducing greenhouse gas emission intensity, efficiently using energy and natural resources, developing green manufacturing, service and consumer sectors; raising awareness, role and capacity of the banking system in granting credit for green economic sectors, developing products and services to support enterprises to adopt green growth.

According to Decision 1604/QĐ-NHNN dated 7/8/2018, the State Bank approved the green bank development project in Vietnam; its main goal was to increase social awareness and responsibility of our banking system about environmental protection, climate change; gradually to make banking activities green step by step, directing credit flows into environmentally friendly project, promoting green manufacturing, services and consumption, clean and renewable energy; actively to promote green growth and sustainable development; to hit the target of 100% banks having internal regulations on environmental and social risk management in credit granting; to apply environmental standards for projects financed by banks; to set environmental risk assessment as a part of the bank's credit granting.

For digital transformation, the spirit of the Industrial Revolution 4.0 has been greatly interested and encouraged by our Party, State and Government. On September 27th, 2019, the Political Bureau issued Resolution No. 52-NQ/TW on a number of guidelines and policies to actively participate in the Fourth Industrial Revolution with the overall goal of "Utilizing effectively opportunities offered by the Fourth Industrial Revolution to promote the process of growth model innovation, economic restructuring in association with the implementation of strategic breakthroughs and national modernization; strongly develop the digital economy rapidly and sustainably based on science - technology, innovation and high-quality human resources; improve the quality of life and welfare of people; firmly ensure national defense, security and ecological environment".

Therefore, on June 3rd, 2020, the Prime Minister signed Decision No. 749/QĐ-TTg approving the National Digital Transformation Program to 2025, with orientation to 2030. That program which has a 10-year vision will completely change our country with goals such as: Developing digital government, improving operational efficiency and effectiveness; by 2030, Vietnam will be in the group of 50 leading E-government; improving competitiveness of the economy; the digital economy will contribute 30% of GDP; the proportion of the digital economy in each industry will be at least 20%; annual labor productivity will increase at least 8%...At the national level, digital transformation is the digital government, digital economy and national digital society. At the local level, digital transformation is the one toward digital local government and society. Successful local digital transformation will contribute to the overall achievement of national digital transformation. Therefore, digital transformation is a task that needs the determination of the entire political system to implement it throughout and synchronously from the central to the locals.

In the banking industry, digital transformation has been strongly promoted. On December 26th 2019, the Governor of the State Bank signed Decision 2655/QĐ-NHNN approving the Strategy for Information Technology Development of Vietnam Banking Sector to 2025, with orientation to 2030, in which the objectives are identified. The goal is to strive that by 2025, 60% of Vietnamese banks will use cloud computing services, by 2030 this rate will increase to 100%. The State Bank also said that in 2021 the State Bank would establish modern retail payment operations connecting with many different industries and fields, in which to focus on payment for public services in order to continue promoting the growth of non-cash payment.

4.2. The current situation of green banking development in the context of digital transformation

In order to catch up with the development trend of modern science and technology, Deputy Governor of Vietnam State Bank, Mr. Nguyen Kim Anh (2018), in charge of Head of the Vietnam State Bank's Steering Committee on Fintech, said that Vietnam banks had actively researched and strongly invested in some technological achievements, including production, services, operations and administration. The most prominent is the practical deployment of digital technologies, such as Cloud Computing, Big Data Analysis, Artificial Intelligence, applications and solutions...They all aim to improve operational efficiency, and to enrich customer experiences.

Mr. Nghiem Thanh Son (2019), Deputy Director of the Payment Department, the Vietnam State Bank, Deputy Head of the Steering Committee on Fintech, said that 81% of credit institutions chose the cooperation model between banks and Fintech companies for mutual development. The exploitation of available advantages of commercial banks, such as brand, larger customer database, risk management capacity ... along with technology experts and breakthrough solutions of Fintech companies... will help two sides improve product efficiency.

According to a survey by the State Bank of Vietnam in September 2020, 95% of commercial banks developed digital transformation strategies or planned to implement this plan in the near future; 39% of banks approved digital transformation strategies; 42% were

developing their own strategies. Most Vietnam commercial banks implemented digital banking at the transformation of processes and communication channels, while the transformation of new data platforms has just been implemented at some pioneering banks. Some typical services of commercial banks can be mentioned as: Digital Lab digital banking space developed by Vietcombank; LiveBank of TPBank; Timo digital banking application of VPBank; Vietinbank has developed a new generation corebank and a modern enterprise data storehouse; MBBank uses ChatBot virtual assistant application available 24/7 on social networks.

As a developing country, Vietnam has been facing the challenges of growth. The cost of hot growth over some past years is environmental pollution, serious ecosystem degradation. According to Dr. Pham Hoang Mai (2015), Director of the Department of Science- Education-Natural Resources and Environment of the Ministry of Planning and Investment, to solve this situation, a huge amount of USD 30 billion was needed for the green growth strategy to 2020. Therefore, in the national strategy of Green Growth, green banks will play a very important role in contributing huge capital. According to the plan, 30% of total capital will be allocated and supported by the budget, the rest will be mobilized from the non-state sector. The development of green credit in our commercial banks positively contributes to the balanced and harmonious development between economy, environment and society; to contribute to hunger eradication and poverty reduction; to avoid ecological risks that many countries had encountered due to too much emphasis on economic growth. On the part of enterprises, green credit development is an opportunity for them to access preferential loans in Vietnam and abroad, as well as receiving long-term support from the State; to avoid environmental risks and contribute to the sustainable development themselves. However, at present Vietnam banks lack experiences in deploying new technologies and credits for new energy; they often consider risks of these projects so high that capital support is not as much as conventional projects. The common "disease" of Vietnam banks today is that focusing too much on collaterals instead of cash flow invested in the projects; they prefer short-term projects, while not approve longer-term energy programs.

Obeying the Government's direction, the State Bank issued Directive No. 03/CT-NHNN dated March 24th, 2015 on promoting green credit growth and managing environmental and social risks in credit granting. Under the plan of the State Bank, from 2015 credit granting should focus on environmental protection, improving the efficiency of natural resources and energy use, improving environmental quality and protecting human health, and ensuring sustainable development.

Recently Decision No. 1604/QD-NHNN on the approval of the Green Bank Development Project in Vietnam aiming to increase social awareness and responsibility of the banking system on environmental protection, climate change, gradually greening banking activities; to direct credit flows into financing environmentally friendly projects; to promote green manufacturing, services and consumption, clean energy and renewable energy sectors; to actively contribute to promote green growth and sustainable development; specifically in 2015, 100% of banks will have internal regulations on environmental and

social risk management in credit granting, 100% of banks will carry out socio-environmental risk assessment; to apply environmental standards for projects funded by banks, and to do environmental risk assessment; at least 10-12 will banks have specialized units/departments in charge of environmental and social risk management; 60% of banks will be able to access green capital and deploy loans for green credit projects. In the Vietnam Banking Industry Development Strategy to 2025, orientation to 2030, issued with Decision No. 34/QD-NHNN dated 07/01/2019, the goal was to promote the development of non-cash payment, optimizing ATM and POS networks; by the end of 2020, the proportion of cash in total payment means will be below 10%, by the end of 2025 this figure will decrease to 8%.

In order to facilitate credit institutions to implement Directive 03 effectively, the State Bank will continue to cooperate with International Finance Corporation (IFC) in developing tools to assess environmental and social risks for some specific economic sectors, in order to support Vietnam banking system. The Vietnam State Bank and IFC will jointly organize training courses on the use of environmental and social risk management tools for core staff at banks.

Currently Vietnam do not have any bank that is considered a 100% green bank. We just have some banks providing green services or lending activities associated with environmental commitments. However, in recent years, under the close guidance of the Government through strategies and orientation documents, many domestic banks have started to pay attention to green credit, such as VietinBank, Techcombank, Sacombank ... They actively deploying green credit products like energy-saving, renewable energy, and clean production loans. According to the State Bank of Vietnam (2020), 19/35 banks have developed strategies to manage environmental and social risks; 19/35 banks have integrated environmental and social risk management into the green credit assessment process; 10/35 banks have built credit products and banking services for the green sector and been interested in granting medium and long-term green credit with preferential interest rates.

4.3. Some typical models of green banking development in the context of digital transformation in Vietnam

BIDV - The Green Bank strives for our community

Throughout its 47-year journey of construction and development, Bank for Investment and Development of Vietnam (BIDV) has always been a pioneer and an example in doing social responsibility, following activities which bring great benefits to the community, and cooperating with the whole society to make living environment green and clean. For its contributions to green growth and sustainable development, BIDV was awarded the Top Ten Sustainable Enterprises in 2018, 2019, 2020 in the field of Trade and Services.

On February 21st 2022, the Agency of French Development (AFD) and Eximbank co-hosted the "Asia-Pacific Sustainable Finance" Forum in Paris (France) and connected to many places around the world. This was an event on the sideline of the European and Asia-Pacific Ministerial Forum. BIDV attended the Forum as AFD's main partner in the Asia-

Pacific region, and one of the key banks arranging and financing many energy development investment projects in Vietnam. At the conference, Mr Tran Long, Deputy General Director of BIDV, on behalf of the bank to represent the topic "Accelerating the Energy Transition: Turning commitments into practical actions", thereby affirming the inevitable trend of developing renewable energy sources to limit greenhouse gas emissions, to protect the environment and to reduce the dependence on fossil fuels.

In order to effectively implement the State Bank's guidance on green bank development, BIDV has urgently studied and approached international practices and recommendations, such as the Safeguard Policy Statement and Gender and Development Policy of ADB, the environmental and social protection requirements of IFC to promulgate the Framework managing BIDV's own environmental and social risks. Since then, BIDV has promoted the framework of its green bank development. Key highlights of this framework include:

(1) BIDV aimed to ensure a strong and transparent commitment for sustainable development, environmental and social protection. Accordingly, the Bank committed to make efforts to promote effective environmental and social risk management practices in all its activities. The Bank committed to finance only projects and business plans designed and operated in accordance with environmental and social protection requirements

(2) BIDV strictly conducts the E&S risk assessment process in parallel with the credit extension process in three main steps: (i) screening business plans/projects; (ii) classify E&S risks; (iii) evaluate E&S risks in details to classify business plans/projects into appropriate groups. For this purpose, based on the Handbook of environmental and social risk assessment guided by the Vietnam State Bank, BIDV has issued its own handbook which is more detailed and easier to apply in the implementation process. All SME employees and relationship managers have been required to follow this process.

(3) BIDV requires all its branches to include environmental and social protection provisions in the Credit Agreement or the Environmental and Social Protection Agreement (which is an annex of the Credit Agreement). Accordingly, customers must commit at least these following: (i) to comply with Vietnamese laws and international social and environmental standards; (ii) to take measures or actions to overcome negative impacts which the projects/business plans has on the environment and society within the agreed period; (iii) to undertake to notify BIDV immediately whenever any incident or accident causes serious impacts on the environment and society, also to develop action plans to remedy such incidents/accidents; (iv) to undertake to provide BIDV with permits and evidences to demonstrate their compliance with socio-environmental commitments. These commitments must be consistently fulfilled during the credit term. Besides, penalty provisions should also be introduced in case customers violate environmental and social commitments. After the loans are approved, BIDV will report and monitor the customer's compliance with environmental and social terms and conditions.

BIDV has also concretized regulations on the implementation of environmental risk assessment when appraising and approving credit grants. BIDV was the first bank to issue regulations on the Environmental and Social Risk Management Framework for projects

financed by the Asian Development Bank (ADB), with which encouraging other projects to apply. In 2021-2022, BIDV coordinated with GIZ (Deutsche Gesellschaft für Internationale Zusammenarbeit) and CBI (Climate Bond Initiative), along with the support of the Vietnam State Bank to develop a standard framework for green bond issuance.

Green credit activities are classified by BIDV into 12 different sectors and there are currently 8 sectors having outstanding loans, focusing mainly on renewable energy, clean energy, waste treatment and pollution prevention. Since 2018, BIDV has decided to stop considering financing coal-fired power projects having adverse impacts on the environment. Until the early 2020, BIDV's total outstanding debt for green projects is more than VND 20 trillion. As of 31/12/2021, outstanding debt of coal-fired power projects decreased to about 110 million USD, and debts has only been collected until the loan term of the projects expired. BIDV's credit scale for renewable energy reached more than \$1,7 billion, accounting for 36% of outstanding loans for renewable energy in Vietnam. BIDV has also made sustainable growth and promoting green growth important goals in the Bank's Business Development Strategy for the period of 2021 - 2025, vision to 2030.

BIDV has successfully mobilized many capital sources to develop green credit from international organizations. One of them was World Bank (WB) for the Renewable Energy Project and Energy Saving Efficiency Project. In May 2021, BIDV was funded by AFD with \$100 million of SUNREF green credit line without government guarantee. In only six months of implementation, 100% of the credit limit has been disbursed by BIDV to support enterprises investing in renewable energy.

Among credit institutions in Vietnam now, BIDV is the only financial organization that can implement the function of "Wholesale Bank" for the "green credit" funded by World Bank through a series of Rural Finance Projects I, II, III, and the Project on Sustainable Agricultural Transformation. Total amount of WB loans was over \$650 million. Under the projects, BIDV provided wholesale loans to credit institutions so that they can directly relend to final borrowers who must meet socio-environmental conditions required by the World Bank.

For more than 20 years, BIDV has maintained and promoted its role as a pioneer bank in efforts to implement, supervise and comply with environmental protection commitments, contributing to building a green ecosystem.

Vietinbank - The action plan

A typical commercial bank in the green banking movement is Vietinbank. According to Mr. Le Duc Tho (2022), General Director of Vietnam Joint Stock Commercial Bank for Industry And Trade (VietinBank), environmental issues may cause businesses to suffer losses, some projects had to suspend operations due to environmental pollution.

VietinBank built a green bank development orientation by issuing a decision to establish the project implementation committee; perfecting appropriate mechanisms and policies to achieve such goals such as: reviewing/updating contents of policies on social environment management in credit granting to suit the Bank's new model; developing annual credit orientation having content on environmental management; building guidelines for appraisal of social environment in credit granting.

In 2011, VietinBank issued environmental - social policies in credit granting activities to regulate the assessment of the impact of plans and projects on the environment - society; to provide solutions to achieve goals of sustainable development. VietinBank's appraisal process currently requires the credit granting bank to assess the impact of the project on the environment - society; to assess the environmental and social security risk of the project before granting credit; to check the loan documents if they have an approved environmental impact assessment; to restrict credit granting for projects that are likely to seriously affect environment - society.

VietinBank has issued an action plan with very specific contents:

(1) To formulate its orientation which is developing "Green Bank" by issuing the decision on establishment of the Project Implementation Committee; to complete appropriate mechanisms and policies towards the following objectives: Reviewing/updating contents of policies on socio-environmental management in credit granting in accordance with VietinBank's new activity model, developing annual credit orientations in which include environmental management, formulating guidelines on socio-environmental appraisal in credit granting.

(2) To strengthen the capacity of staff in the implementation of "Green Banking - Credit" by organizing training and propaganda in order to raise awareness on this slogan, efficient energy and natural resources use and saving and environmental protection.

(3) To find and build up solutions to promote "Green Bank - Credit" products, supporting businesses to implement green growth; to encourage the focus on bank credit capital for projects and business plans which mitigate and adapt to climate change; to develop modern banking services using high technology and being environmentally friendly.

Since 2015, VietinBank has promoted activities to seek global preferential capital to finance green sectors. The most important result VietinBank got was the signing of a cooperation agreement between the Bank and IFC. This agreement will create abundant capital for VietinBank to implement preferential policies. IFC also supports the Bank with knowledge and experience in financing and implementing Green Credit loans. Under this agreement, VietinBank determined to give priority to green credit for projects promoting CO₂ emission reduction and energy saving. In the framework of their cooperation, IFC has supported VietinBank to develop an effective energy financing strategy, coordinating with a specialized team at VietinBank to organize professional training on appraisal and lending for energy saving projects, and to build energy-saving financing products. Besides, VietinBank also actively approaches green international capital through focal points such as the World Bank, Asian Development Bank, European Investment Bank...

VietinBank has granted credit to enterprises investing in machinery and equipment, supplementing working capital for producing and trading environmentally friendly and good-health products. Programs oriented by the Government and the State Bank have been also quickly implemented by Vietinbank such as: Rural Agriculture Loan under Decree 55, High-tech Clean Agriculture Loans, Supporting Industry Loans...

Corporate customers operating in the green sectors have been actively applied preferential policies by VietinBank through appropriate credit products/programs such as:

Accompanying with Corporate customers, VietinBank SME Stronger on preferential package of interest rates and fees... Among these VietinBank's plans are optimizing capital efficiency, improving operational efficiency, expanding production and business, increasing incentives based on industry-specific.

VietinBank has also actively built up credit products, incentive programs, insurance combos for solar power projects, guidelines on granting credits for solar farm and wind power projects. Credit products have been made specifically for each specialized industry such as: Unsecured loans on the cash flow management from export contracts; import-export factoring, agricultural chains to provide financial support for individuals and organizations. For individual customers the Bank has applied lending policies for cultivating and taking care of seasonal crops and livestock.

By the end of June 2020, VietinBank's total outstanding loans in the agricultural sector reached around VND 140.000 billion, focusing mainly on financing clean agricultural projects with the proportion accounting for 70% of outstanding loans. For the implementation of green credit, the Bank achieved many positive results with more than 600.000 green credit financing contracts, the total green credit balance reached approximately VND 17.000 billion (accounting for 12% of total outstanding loans in the agricultural sector). Among them, the fields of renewable energy, clean energy, sustainable water management in urban and rural areas, waste treatment and pollution prevention accounted for 98% of total outstanding loans.

5. Discussion and Conclusion

Building up long-term development strategies

In order to widely and effectively develop the green banking model in Vietnamese society, along with the green growth of our whole economy, we need to have a comprehensive study to build up long-term green banking programs for restructuring banking sector on the basis of national macroeconomics and protecting the community ecological environment. Accordingly, specific action plans need to be implemented with particular progress and expected results. To do so, it is necessary to have the direction and support from the Government and the State Bank of Vietnam in their guidelines, policies, mechanisms... as well as the efforts of each Bank in our country.

The State Bank should develop an appropriate development roadmap and mechanism to facilitate commercial banks to deploy more products of digital transformation. In the process of building and proposing solutions to complete the Fintech ecosystem in Vietnam State management agencies in general, and the State Bank in particular, need to create favorable conditions for Fintech businesses to develop fast and sustainably. Be noticed that these conditions must be in line with the Government's policies and orientation towards a digital economy in the future.

Commercial banks should have long-term development plans to take advantage of the technological advances of the Fourth Industrial Revolution, to continue to implement new payment models in urban, rural, and remote areas. Domestic banks should actively cooperate with foreign financial groups and banks to develop green banks because large

multinational banks such as HSBC, ANZ ... can accelerate the green movement towards a sustainable future.

As a developing country, Vietnam should learn experiences of the world's leading countries in developing green banking and green credit, applying advanced technologies and solutions which are suitable to our country's circumstances and potentials. Today the model of local banking is popular in the world, which can be applied well to many regions of Vietnam, especially locals whose economy is less active than others. A local green bank will be a great source of support for local green society, education, housing..., creating great and direct benefits for the community.

Raising awareness

Currently the concepts of green finance and green banking in Vietnam are still new. Green finance solutions are very few. There are not many green banking solutions in the green growth strategy. Traditional commercial banks are not ready to provide green financial products and services. Therefore, the State Bank and our Government need to raise banks' awareness about the benefits and efficiency of providing green credit and capital.

Once green banking become a popular model in people's awareness and actual operation of commercial banks, business standards and social responsibility of banks and credit institutions will be higher and higher. Our community will benefit more from ethical business practices and protecting living environment.

Improve the legal system of Vietnam

In order to meet modernization wave of digital transformation, the Vietnam State Bank needs to continue reviewing, revising and completing its legal system in order to facilitate and support the development and operation of digital banks; supporting and promoting new products and services; building up a legal environment to promote innovation of Fintech organizations, to encourage safe and effective Fintech solutions.

The banking industry should continue to actively implement the Prime Minister's Directive No. 16/CT-TTg on enhancing capacity to approach the Fourth Industrial Revolution, in which focus on completing the legal corridor to support payment activities, payment systems, security for banking operations; increasing investment in upgrading IT infrastructure and national interbank payment system. A very important issue that the banking industry should focus on is the training for human resources to be able to adapt very high requirements of digital transformation. In the long term, it is necessary to study and complete the legal framework for securities trading, settlement and clearing when new transaction and payment models (such as payment through e-wallets, clearing in the blockchain system) are formed by the application of technology. At the same time, our legal agencies should open legal regulations relating to information security and information security.

Aligning green banking with banking culture

Applicating green banking models will contribute to create a culture in customers' use of banking services. When using banking services becomes more convenient, preferential and less expensive (through online banking, green accounts and green credit

cards...), consumers will tend to use them more and more. This will raise social awareness in the use of banking services, creating a future society where financial and banking services become an indispensable part of daily life.

Investing in technology infrastructure

Commercial banks need to be more active in modernizing information technology systems, upgrading new-generation core banking system, investing in fundamental technologies of the industrial revolution 4.0 to meet the development trend of digital banking...; constantly researching and applying new breakthrough solutions (such as innovative payment solutions, mobile payment via QR code, digitizing card information, chip payment technology...), building up connection platforms, sharing open data through application programming interface (open API), Big Data Analytics, Artificial Intelligence ... in order to provide convenient, reasonably priced banking products and services in the direction of digitalization and intelligence, bringing practical benefits to customers in the digital era.

Green banking and green accounts require a high level of technology to serve online services, and to meet diverse needs of customers. Therefore, to develop online banking system and green payment accounts, commercial banks must be equipped with modern information technologies in the world today, they must have high-quality human resources to use and operate their systems.

IMPACT OF CLIMATE CHANGE ON SOCIO-ECONOMIC ACTIVITIES IN VIETNAM

Nguyen Vu Tram Anh

anhnvtt@ueh.edu.vn

Vo Thanh Truc

trucvt@ueh.edu.vn

Faculty of Management, UEH University-Vinh Long Campus, Vinh Long, Vietnam

Abstract

In recent decades growth has been based on the exploitation of natural resources; competition, scramble for resources to serve the growth needs, causing resource depletion, environmental pollution, climate change. Climate change has negative impacts on economic and social development. The socio-economic losses due to the impacts of climate change plus the costs of repairing damage reduce the economic growth of many countries, including Vietnam. Climate change will reduce economic growth and create unsustainable growth cycles, climate change will seriously affect productivity and output of industries such as energy, industry, , transportation, agriculture - forestry,... Climate change is tending to cause a lot of damage to the economy and society of Vietnam. Therefore, in order to be able to stabilize and develop socio-economic in the current period, preventing the negative impacts of climate change as well as implementing response solutions is becoming an urgent task every day. head to Vietnam.

Keywords: *Growth, economy, society, climate change*

1. Introduction

Until now, although the quality of economic growth has been paid more attention, GDP growth rate is still an important indicator to assess the health and size of the economy. The race to achieve high GDP is approaching the limit of nature's tolerance, causing environmental pollution and climate change. In turn, climate change reduces economic growth, causes instability to social security and becomes one of the global non-traditional security problems, threatening the survival of the world. of humanity.

Experts say that climate change is tending to cause damage to a number of countries, especially coastal countries. Therefore, preventing the negative effects of climate change as well as implementing response solutions is becoming a top urgent task for many countries, including Vietnam.

According to worldbank.org 2022 After more than two decades of steady growth, Vietnam has set an ambitious goal of achieving high income by 2045. According to the Socio-Economic Development Strategy 2021-2030, The outcome of the country's economic transformation will depend heavily on effective management of natural capital - the vast

reserves of agricultural, forest and mineral resources that have helped drive development in Vietnam. However, with more than 3,200 km of coastline, many low-lying cities and river deltas, Vietnam is one of the most vulnerable countries in the world to climate change. The effects of climate change - primarily higher temperatures and sea levels and greater volatility - have been disrupting economic activity and undermining growth. Initial calculations show that Vietnam will lose \$10 billion by 2020, or 3.2% of GDP, due to the effects of climate change.

Without appropriate mitigation and adaptation measures, it is estimated that climate change will cost Vietnam between 12% and 14.5% of GDP per year by 2050 and could put up to one million people in extreme poverty by 2030. In the face of climate change, reality requires appropriate policies to adapt and mitigate the impacts of climate change and protect the environment for sustainable development. In the long term, it can help Vietnam develop a strategy to respond to climate change in the future.

2. Method

Analytical methods: Statistical methods, mathematical modeling methods, synthesis methods, inheritance are used to build the report.

Data collection method: The data used in the Report are inherited from the project "Update scenarios of climate change and sea level rise for Vietnam" under the Target Program to respond to climate change and green growth in the period 2016-2020. The data on temperature, precipitation at 150 meteorological stations and sea level data at 15 hydrographic stations were collected from the year starting with data from 1958 (for monthly data) and from 1961 (for monthly data). daily data) to 2018, some data related to extreme weather events will be updated to 2020, climate change scenarios to 2100 climate change assessment reports of the Ministry of Natural Resources and environment.

3. Impact of climate change on socio-economic activities in Vietnam

Under the impact of climate change, the frequency and intensity of natural disasters is increasing, affecting living conditions and socio-economic activities; causing a lot of loss of life, property, infrastructure, economy, culture, society, bad impact on the environment.

3.1. The impact of climate change on agriculture

The impact of climate change on agriculture is assessed for the fields of cultivation, animal husbandry, forestry and fishery in terms of the impact on productivity, production of livestock and crops.

3.1.1. Crop

The average yield of some crops (rice, maize, sweet potato, soybean, sugarcane) is the average national average in the base period and the periods 2016-2035, 2046-2065, 2080-2099 according to the scenario scenarios. Representative Concentration Pathways RCP4.5, RCP8.5 and changes in crop yield over time under climate change scenarios compared to baseline are presented in Table 1.

Table 1. Crop yield under national average scenarios

Ordinal number	Climate Zone	1986-2005	Scenario RCP4.5			Scenario RCP8.5		
			2016-2035	2046-2065	2080-2099	2016-2035	2046-2065	2080-2099
Crop yield (ton/ha)								
1	Winter-spring rice	4,83	5,50	6,18	6,71	5,51	6,45	7,55
2	Seasonal rice	3,67	4,16	4,58	4,82	4,21	4,80	5,46
3	Corn	3,73	4,26	4,77	5,01	4,29	4,97	5,86
4	Sweet potato	7,14	7,93	8,73	9,14	7,96	9,05	10,33
5	Soybean	1,48	1,68	1,88	1,98	1,69	1,96	2,32

Source: Climate change assessment report of Department of Natural Resources and Environment, 2021

On average for the whole country, crop productivity in the periods under the scenarios RCP4.5 and RCP8.5 both increased compared to the baseline period and increased gradually over the periods 2016-2035, 2046-2065. and 2080-2099. Particularly for sugarcane, the yield increase is much less than that of other crops with a gradual increase over the periods 2016-2035, 2046-2065 and 2080-2099 under the RCP8.5 scenario; the rate of increase gradually decreased through the periods 2016-2035, 2046-2065 and increased sharply again in the period 2080-2099 but still smaller than the period 2016-2035 under the RCP4.5 scenario (Table 1).

Considering the average of climate zones, yield of winter-spring rice, summer rice, maize, sweet potato and soybean in the periods under the scenarios RCP4.5 and RCP8.5 all increased compared to the baseline period and the level increasing gradually over the periods 2016-2035, 2046-2065 and 2080-2099 in all 7 climate zones.

3.1.2 Animal husbandry

Climate change, storms, floods and extreme weather events such as abnormally hot sun, extreme cold, and severe cold seriously affect the health, fertility, growth and development of livestock, poultry. In addition, climate change also reduces the supply of

feed for livestock. Severe cold, harmful cold kills a series of livestock and poultry in the plains, midlands and mountainous areas. Only in the first 6 months of 2016, 44,000 poultry and 20,000 cattle died due to the effects of droughts in the Central Highlands, South Central Coast and Mekong River Delta [4]. Unusually hot weather reduces livestock productivity; increase feed costs, energy costs for cooling; reduce the resistance of cattle and poultry. Sea level rise and saline intrusion make the area of grass land shrink, affecting the source of food for livestock. Climate change impacts on livestock include changes in production and quality of animal feed and feed, increasing disease outbreaks [5]. The impact of climate change on pig production is expected to reduce the total pig herd by 1.1% due to climate change in Vietnam [11].

In the winter-spring crop of 2007-2008, the number of cattle that died from hunger and cold was over 200,000; In the 2010-2011 Winter-Spring crop, severe cold and damaging cold lasting for more than 40 days caused great damage to livestock in the provinces, with a total of over 90,000 dead cattle. In recent years, due to the proactive prevention of natural disasters, the number of victims has decreased year by year.

3.2. Forestry

Under the impact of climate change, changes in temperature and precipitation are directly related to and affect forests and forestry [14].

Millions of hectares of bare land, bare hills have lost forests for many years, the physical and mechanical characteristics of the soil such as porosity, cohesion, permeability, nutrient content and microbial content are significantly reduced, the soil becomes dry, hard, compacted, unsuitable for cultivation. Topsoil becomes susceptible to erosion, leaching, accumulation of iron and aluminum, causing caking and laterite formation, and the ability of agro-forestry production is severely reduced [14].

Climate change threatens forest biodiversity, increases the risk of deforestation, the risk of conversion of forest land use and thus increases the risk of greenhouse gas emissions. Increased temperatures and reduced rainfall will increase the risk of forest fires, increase disease outbreaks and reduce the ability of forests to withstand the effects of climate change. Climate change will change the nesting and structure of some types of forests, forcing species to migrate and find ways to adapt to new living conditions. Climate change will increase the risk of extinction of some plant and animal species, making it difficult for biodiversity conservation. Some species, if they cannot adapt to their new habitat, will forever disappear from the planet. According to forecasts, by 2070, tropical plants in the high mountains will be able to live at an altitude of 100÷550 m and move northward 100÷200km (Vietnam Initial NatCom, 2003) [14]

The area of dipterocarp forest in the Central Highlands is likely to shrink rapidly, accounting for about 1.5% of the current area and sharply reduced by 2100. Climate change may cause more severe drought in the dry season, causing loss of land. characteristics of the dipterocarp forest. Large tree species may gradually disappear and the land will become increasingly arid and deserted instead. Dipterocarp forests can easily become grasslands,

poor. The total area of suitable climate zone for dipterocarp forest is only about 300,000 ha, or about 0.9% of the national natural forest area (compared to 1.2% in 2000) [20].

3.3. Seafood

- Impact due to increased temperature

Temperature has a great influence on the growth and development of cultured aquatic animals. Temperature affects the metabolic rate, reproductive rate and development of aquatic organisms. Research results show that, if the number of hot days above 35°C in a year increases by one day, it will reduce shrimp production next year by 0.4%, two years later by 0.6% and three years later, decreased by 0.4% (Institute of Fisheries Economics and Planning, 2016).

- Impact of rainfall change

Some studies have shown that a sudden increase in rainfall causes salinity in brackish water ponds to drop rapidly, causing "sweet shock" for farmed shrimp as well as changing pH in ponds or rainwater from Surrounding water bodies pouring down will bring pollutants to the farmed animals, on the other hand, heavy rain will cause flooding, overflowing banks and washing away aquatic species.

- The impact of extreme climate events

Storms and tropical depressions will wreak havoc on the infrastructure of the farming area such as landslides, dikes, irrigation canals, tents, supplies and equipment, or cause great damage to fishing boats at sea.

- Impact of sea level rise

Sea level rise often affects fishery production in two aspects. Firstly, it causes saltwater intrusion in coastal areas, leading to changes in salinity in aquaculture and feed water bodies, leading to changes in the habitat of aquaculture species in brackish water and freshwater adjacent to the sea. At that time, the structure of cultured subjects will have to change to adapt to the change of salinity in the water source. The second is the impact of sea level rise in combination with storm surge, often causing great consequences and damage to coastal fisheries infrastructure, damage to fishing boats, damage to coastal aquaculture cages. sea, road landslides, broken dykes surrounding farming areas, overflowing banks causing loss of farmed fish and shrimp, deterioration of water quality. [3].

3.4. Impact of climate change on industry

Industries, especially the processing and manufacturing industries, will be affected by climate change due to the source of raw materials for industry, especially raw materials for the food processing, textile and garment industries. will be significantly reduced due to lack of supply from raw material areas in the Mekong Delta provinces, which are expected to suffer the heaviest flooding. This will put pressure on the restructuring of industries in terms of industrial type, proportion of processing industry and high technology.

Rising temperatures lead to increased energy consumption in industries: increasing ventilation and cooling costs for mining pits and reducing the efficiency and output of power

plants. Electricity consumption for domestic use increases and cooling costs in commercial industries also increase significantly as temperatures tend to increase.

Irregular rainstorms and sea level rise will negatively affect the operation and exploitation of power transmission and distribution systems, drilling rigs, inland oil and gas pipelines, and oil supply to oil tankers. ; increase the cost of maintenance and repair of energy facilities; affecting the supply and consumption of energy and national energy security. [10].

3.5. The impact of climate change on cities

Climate change is a major threat to urban infrastructure and quality of life. In the context of climate change, cities are predicted to be more severely impacted due to the increase in intensity, frequency and severity of natural disasters. Depending on geographical location and exposure to natural disasters, urban areas in Vietnam will be affected differently. Urban types include industrial zones, economic zones and cities in different geographical regions including from North to South; and different terrains including coastal, midland, mountainous and lowland areas.

Urban areas including industrial zones and economic zones distributed in the West and in the main river basins will be affected by floods and inundation. Cities in coastal areas are vulnerable to disasters related to storms, floods and sea level rise, increasing risks to urban assets, livelihoods and infrastructure. Urban areas, industrial zones, coastal economic zones and urban areas in the Mekong Delta will be mainly affected by sea level rise. The area from the North to the South-Central Coast is affected by tropical depressions and storms, but coastal cities are affected by storms more seriously than other urban areas. Midland and mountainous urban areas in the North and Central are often affected by circulation after storms, causing floods, flash floods and landslides [2]. In urban areas, solid waste treatment systems and systems Urban water supply and drainage systems are the key objects affected. Increased rainfall will cause flooding of storage points, routes of collection, transportation, transshipment, and disruption of solid waste treatment at some point in time. Climate change also affects water supplies (surface water, groundwater) and water supply systems including focal works and water supply networks [6].

Climate change and urban development are closely related and often interact negatively. Rapid urban development has a strong impact on nature and increases the frequency and severity of natural disasters. The strong development of urban areas, energy use and construction of infrastructure, high-density buildings... all turn cities into energy consumers and create many pollutants. When the ground is gradually "concreted", the space is occupied, the water permeability of the city in the event of heavy rain will decrease. The loss of water collection areas to save land for construction makes existing urban areas and newly planned areas increase the likelihood of flooding due to heavy rains.

3.6. Impact of climate change on transportation

Transport plays an important role in the socio-economic activities of each country, especially for a country with an emerging economy like Vietnam. In the last two decades, Vietnam's transport network, although invested and expanded, is increasingly facing the risks of

various types of natural disasters and climate change [13]. Because the road transport network has a high exposure to climate change, the analysis focuses mainly on the road transport system in the regions of mainland Vietnam, bordering China to the north, Lao PDR and Cambodia to the west, accessible by road and surrounded by coastal roads to the east and south.

Among types of natural disasters, floods, flash floods and landslides pose many potential risks to the transportation industry. The road sector was identified as the hardest hit, followed by railways and inland waterways. Under climate change scenarios, up to 14.5% of the total length of the national highway network is at high risk of flooding, mainly concentrated in the Dong Nai river basin and part of the region. Southwest region; There are 14/936 road bridges, accounting for 1.5% in the medium flood risk area and 0.7% in the high flood risk area [1].

An increase in rainfall will make 20% of the total length of the national highway network at risk of landslides, mainly concentrated in the northern mountainous areas and the Central Highlands; There are 458 out of 936 road bridges, accounting for 49% of the average landslide risk area and 4% of the high risk area. About 20% of the total length of the railway network is at risk of flooding, mainly concentrated in the central coastal area. Increased rainfall will make 8.8% of the total length of the railway network at high risk of landslides, mainly concentrated in the North - South railway line, the Central section [106].

According to a report by the Ministry of Transport in collaboration with the World Bank and the German Organization for International Cooperation in 2019, about 20% of the transport network will be vulnerable to disaster risks and climate change. resulting in losses of up to \$1.9 million per day for road incidents and \$2.6 million per day for railway incidents. Roads are the object most affected by flooding and the railway system is most affected by landslides. According to the RCP4.5 scenario, about 786÷1,180km of national highways, 97÷121km of railways will be affected by flooding, 222km of national highways in 15 northern provinces are likely to be affected by flash floods, and 320km of roads will be affected by flash floods. National highways in the northern provinces are at risk of landslide impacts. The research results show that in the future for roads, important sections of National Highway 1A are mainly exposed to risks from landslides and storms, while floods due to rising river water affect other areas. linked around Ho Chi Minh City and Thua Thien-Hue, flash floods affected several mountainous provinces. For railways, important sections of the railway network are at risk mainly from landslides and storms, while river floods affect a small section of the link near Quang Nam and Thua Thien Hue provinces. [13].

3.7. Impact of climate change on energy

The energy sector accounts for nearly two-thirds of total global greenhouse gas (GHG) emissions and is a major driver of climate change [22]. Conversely, climate change is also having significant effects on the sector. The phenomenon of abnormal weather and extreme climates occurring frequently and irregularly has strongly affected energy supply and demand, directly affecting the coal, power generation, oil and gas industries and threatened insecurity. energy security of the country. Climate change not only further

increases the level of energy dependence, especially import demand, leading to supply instability as well as geopolitical dependence, but also has a great impact on security. secure and stable energy supply, interrupting, stagnation, and even paralysis for a long time [19]. As for the power system, when the air temperature increases, the load of the power system increases, leading to the power plants, power lines and power stations having to operate with higher intensity. For coal, oil, gas, biomass and nuclear power plants, when the air temperature increases, the water temperature increases, leading to an increase in the circulating water cooling the condenser, reducing the turbine efficiency- bin, which wastes fuel.

The increase in air temperature leads to an increase in energy consumption demand due to the use of many cooling devices. The forecast results of climate change impacts show that in 2030, primary energy demand will increase by about 391.7 thousand tons of oil equivalent, accounting for 0.17% of total primary energy demand in 2030 [9]

Increased rainfall has a positive effect on hydropower plants in increasing the capacity of hydropower plants, storing water for reservoirs. The electricity output of hydropower in the period 2080-2099 increased by about 4% compared to the background period. However, abnormal rainfall and flows also affect the ability of hydroelectric plants to supply and regulate electricity production plans; causing damage, damage to the electricity supply infrastructure, increasing the cost of new investment, renovating, repairing and upgrading equipment, electricity distribution network, oil rigs built on the sea, Oil and gas transportation systems, and gas-fired power plants built along the coast are also affected.

3.8. Impact of climate change on public health

So far in the world in general and in Vietnam in particular, there have been significant improvements in the health of millions of people. Maternal and child mortality rates have decreased, global life expectancy has continued to increase, and the fight against a number of infectious diseases has made some progress [21]. However, climate change is threatening the gains already achieved in reducing the global burden of disease and vulnerability.

High air temperature, long-lasting heat waves as well as extreme weather events tend to increase, increasing negative impacts on human health, especially the elderly. age, people with diseases such as cardiovascular, high blood pressure, neurological, musculoskeletal, respiratory, allergies, asthma, sinus. According to statistics, when the average temperature increases by 1.0 °C, the hospitalization rate of children aged 0÷2 increases by 3.4% and the hospitalization rate of children aged 3÷5 increases by 4.6. %. When mean temperature increased by 1.0 °C, the rate of hospitalization in children under 5 years old due to respiratory infections increased by 3.8% [18].

Climate change affects human health indirectly through the sources of infectious diseases because vector-borne diseases are related to climate characteristics such as temperature, humidity, rainfall, wind intensity. . Climate change creates favorable conditions for disease vectors to develop, increasing the likelihood of outbreaks and spread of diseases such as influenza A (H1N1), influenza A (H5N1), influenza A (H7N9), diarrhea, and cholera. , dysentery, malaria, dengue fever, yellow fever, typhoid, viral encephalitis, Japanese encephalitis, severe acute respiratory syndrome (SARS), plague, Zika [16, 17].

3.9. Impact of climate change on tourism

Tourism is an economic sector that is sensitive to natural environmental conditions, so tourism is one of the industries most heavily affected by the impacts of climate change and sea level rise. In Vietnam, most tourism activities are related to climate change factors such as location and size of coastal tourist areas affected by sea level rise, storm surge, number of Sunshine hours, rainfall, and temperature background affect the organization of tourism activities [7]. Research by the Institute for Tourism Development shows that climate change directly affects tourism development in three aspects: tourism resources, tourism infrastructure and travel activities.

Tourism resources include tourist attractions, including natural tourism resources that have been formed and existed for millions of years such as Ha Long Bay, Phong Nha - Ke Bang National Park as well as other tourist areas. historical - cultural sites, scenic spots. Because the distribution of tourism resources is concentrated mainly in the coastal areas, on the islands - where the exposure to climate change is high, the impacts are expected to increase [23].

Climate change also adversely affects the infrastructure, technical facilities of tourism and travel activities. Tourist service works are damaged or degraded under the impact of strong storms and floods. Heavy rain accompanied by strong winds, storms or high temperatures also causes rapid deterioration of architectural materials, damage to the transportation system, accommodation facilities, and amusement parks.

Any change in climate and weather will also cause impacts on tourism activities, especially travel activities are often affected, delayed or even canceled due to bad weather conditions: storm, flood, flood, flash flood. Climate change increases extreme weather phenomena and directly affects passenger transport, especially by air (according to statistics of the World Tourism Organization, over 60% of tourist arrivals international travel between countries is by air) [15].

In addition, climate change has indirect impacts on tourism activities through other sectors such as transport, energy, water management, land use (for tourism services).

4. Discussion and Conclusion

4.1. Solutions to adapt to climate change

4.1.1. Local authorities need to monitor the climate and give early warning of natural disasters

To do that, local authorities should improve:

- Institutional system, promulgating and implementing Law on natural disaster prevention and control, Law on hydrometeorology as well as sub-law documents; while implementing investment strategies, programs and projects, climate change and sea level rise monitoring systems should also be built and operated effectively. Hydrometeorological forecasting technologies also need to be developed, gradually approaching the level of advanced countries in Southeast Asia, especially in forecasting and warning of storms, heavy rain, severe cold, and damaging cold. , floods and heat waves.

- Strengthening hydrometeorological stations and stations such as meteorological stations, automatic radiation measurement stations; agricultural meteorological station; global climate monitoring stations, etc. and these hydrometeorological stations in addition to measuring rain, hydrometeorological monitoring stations should have a high rate of automation to ensure timely provision and improve accuracy. accurate about Vietnam's storm forecast bulletins in order to contribute to reducing damage compared to the past and raising the level of Vietnam's storm forecasting compared to advanced countries in the region and the world.

- Forming an earthquake and tsunami warning system to guide people to respond to tsunamis, tropical depressions, storms and other types of natural disasters in accordance with the actual situation in the locality.

4.1.2. Responding to natural disasters, preventing flooding for big cities, strengthening river and sea dykes and reservoir safety

The Government needs to promulgate and implement development plannings and construction regulations in disaster-prone areas. Key and urgent disaster prevention works should be consolidated and built to contribute to reducing damage. damage caused by natural disasters in the near future.

The Ministry of Agriculture and Rural Development should have a plan for dyke maintenance and repair for provinces and cities with dikes from grade III to special grade; promulgate guidelines on technical requirements in dyke maintenance and repair; strengthening local capacity in dyke protection, getting ready for dike protection and flood control; applying science and technology in upgrading, repairing, inspecting and monitoring natural disaster prevention works.

4.1.3. Ensuring food security

To ensure national food security, especially in the context of climate change, local governments should:

- Restructuring crops, developing large-scale agricultural production in order to contribute to the growth of high-value industrial crops. In addition, a disease control system should be developed and promulgated for most crops and livestock that are suitable for natural and climatic conditions, in which the crop and livestock management agency (including aquaculture) should provide guidance and recommendations on prevention and control of diseases caused by changes in weather and climate.

- Construction of irrigation works in service of production restructuring to implement irrigation works to irrigate upland crops, high-value industrial plants and to serve aquaculture.

4.1.4. Building effective communities to adapt to climate change

Local authorities need to strengthen the capacity and participation of communities in climate change response activities:

- Sustainable livelihood development in the context of climate change: Localities throughout the country need to focus on developing and diversifying livelihoods through

activities such as changing the structure of crops and livestock, changing the structure of plants and animals. scope and scale of production, application of technology transfer...in order to adapt to climate change

- Improving community health and ensuring access to basic health services: strengthening the capacity of the health system, modernizing equipment, improving the capacity of health workers should be taken care of.

4.1.5. Forest protection and sustainable development and biodiversity conservation

Local governments need to develop forests, improve forest cover, improve forest quality, conserve biodiversity, and protect and conserve genetic resources and potentially extinct species.

4.2. Solutions to mitigate climate change

4.2.1. Energy

The Government of Vietnam needs to reduce greenhouse gas emissions in energy production facilities and large energy storage facilities in the direction of promoting economical and efficient use of energy, promoting the development of energy sources. the amount of available apples, associated with reducing greenhouse gas emissions, diversifying supply and reducing the need to import coal and oil for power production in order to fully exploit renewable and inexhaustible natural resources in Vietnam. South, reducing pressure on the national power system, increasing economic benefits for the locality.

- Eliminate inefficient, climate-unfriendly technology in industry, energy and transportation; a list of alternative technologies with appropriate emission criteria that can ensure environmentally sustainable development and improve air quality, especially in big cities.

4.2.2. Waste

The Ministry of Construction needs to conduct research on domestic waste management models in urban and rural areas to minimize environmental pollution and reduce greenhouse gas emissions. For the management of solid waste, hazardous waste (after-use pesticide packaging), a number of new mechanisms and policies on electricity production from waste, construction waste management, control control of waste from plastic bags, recovery of discarded products, use of ash and slag, etc... should be issued.

4.2.3. Industrial Process

To initially reduce emissions in the industrial process, the Ministry of Construction needs to conduct research and apply solutions to reduce CO₂ emissions in the industry of producing cement and other building materials such as glass, bricks, and tiles. , roofing sheet...; and research and develop green building materials and products (saving energy, reducing greenhouse gas emissions and reducing environmental pollution) and issuing an Action Plan to reduce greenhouse gas emissions in the industry. cement industry to 2020, with a vision to 2030.

4.2.4. Solutions to increase financial resources

Central and local state budgets, including ODA, for climate change adaptation and GHG emission reduction should be appropriately allocated to target programs related to climate change adaptation. climate change.

The Government should have solutions to increase scientific and technological resources, promote research, encourage technology transfer and effectively apply modern scientific and technological achievements, new fuels and materials in the field of science and technology. reducing greenhouse gas emissions and adapting to climate change, enhancing the competitiveness of key economic and manufacturing sectors towards developing a low-carbon economy and green growth.

4.2.5. Solutions to enhance international integration and cooperation

Vietnam continues to implement previously signed international treaties such as UNFCCC, Kyoto Protocol, Vienna Convention on the protection of the ozone layer, Montreal Protocol on substances that deplete the ozone layer, and the Protocol on substances that deplete the ozone layer. Montreal protocol.... Expanding cooperation relationship with many countries and regions, regional/regional frameworks and international forums on natural resources and environment. In addition, Vietnam also needs to mobilize international support from many climate change response support programs to support policy development on climate change response in Vietnam and mobilize resources to respond to climate change. resources for the state budget.

4.3. Conclusion

Climate change will cause many adverse effects on natural resources, environment and socio-economic development of Vietnam. However, the implementation of measures to respond to climate change will also have positive effects on the implementation of the country's socio-economic development goals.

The analysis shows that the impact of climate change on Vietnam's socio-economic is very large. Therefore, the implementation of climate change response and mitigation actions is important and necessary, contributing to promoting the development of renewable energy; develop agriculture, forestry and fishery highly adaptable to weather conditions; access and receive many sources of technical and modern scientific and technological support as well as financial support from international organizations; improve the quality of human resources in the country. Besides, it also helps Vietnam to fulfill its commitments on climate change with the international community. Assessing the benefits of actions to respond to climate change also provides a scientific basis to promote and attract domestic and foreign business investment activities for the field of climate change, contributing to bring the benefits of climate change and promote green and sustainable socio-economic development in Vietnam.

THE CRITERIA FOR THE DEVELOPMENT OF A ZERO-EMISSION PORT - GREEN PORT

Dang Manh Ha

hadm.vnldv@gmail.com

Vietnam Maritime Corporation, Hai Phong city, Vietnam

Nguyen Thi Thuy Hong

hongntt.ktc@vimaru.edu.vn

Faculty of Economics, Vietnam Maritime University, Hai Phong city, Vietnam

Abstract

Green ports nowadays play a critical role in the development of a sustainable business plan that comprehends the ecological and financial workings of environmental incentive programs. The major goal of this study is to identify the standards and significant factors that influence the growth of green ports. The findings demonstrated that a variety of crucial factors, including the availability of technical innovation, environmental regulations, financial incentives provided by governments, and the collaboration of parties concerned, had an impact on the development of green ports in developing countries. The implications and discussion will be covered in great length in the study.

Keywords: *Green Port; Drivers; Regulations; Technical Advancement; Sustainability*

1. Introduction

Ports have a substantial impact on both domestic and foreign commerce as well as economic growth since they are crucial nodes in the global transportation network (Bjerkan et al., 2021). For instance, the Vietnamese economy relies heavily on ports, which lets the nation present itself as the "new Asian tiger". In the first four months of 2022, almost 236 million tons of goods passed through the ports, an increase of 3% over the same period in 2021 (Vietnam Maritime Administration, 2022). In 2021, goods were exported and imported for a combined sum of 668.5 billion USD.

Despite their significance, ports have negative environmental impacts. The main factors contributing to the air, water, and soil pollution around ports are port operations and marine traffic (Kwon, 2022). Evidence from Corbett et al. (2007) showed that greenhouse gases (GHGs) and other pollutants from maritime transportation were mostly to blame for the 60,000 annual mortality from lung cancer and cardiovascular illness across East Asian, South Asian, and European countries (Wang et al., 2020).

Various approaches have been developed over the past few decades to stop or minimize the emissions and associated external costs caused by shipping, particularly at ports that are adjacent to densely populated areas (Spengler and Tovar, 2021). The term "green port" was first used by the United Nations in 1992, but it has only recently gained

popularity as it has become clear that seaports must cut back on emissions from both current and future operations in the port region as well as the larger logistics area (Lam and Notteboom, 2014). In addition to focusing on pollution control and other environmental measures, ports must also continue to emphasize port growth (Fahimnia et al., 2015). A green port strategy should accomplish both economic and environmental objectives in order to achieve sustainable growth (Hossain et al., 2019). In order to comply with state and municipal environmental legislation, the port must incorporate corporate social responsibility (CSR), port strategy, and CSR.

Port sustainability studies have mostly concentrated on Asian countries including China, Vietnam, and Cambodia although European ports have garnered a lot of attention (Le et al., 2014; Tseng and Pilcher, 2019). Chen and Pak (2017) discovered a set of realistic and helpful sustainable performance evaluation indicators for Chinese ports like Shanghai, Ningbo, and Qingdao ports using the Delphi approach. Additionally, environmental issues including SO₂ emissions and the Kaohsiung Green Flag Incentive Program have been the focus of study in Taiwan (Chang and Jhang, 2016; Liu et al., 2014). Academic research has mostly focused over the past 10 years on how challenging it is to reduce emissions from ships and ports. The main issues revolve around reducing emissions from ships at sea, which between 2007 and 2012 accounted for 2.8% of global GHG emissions, or double that produced by air travel, primarily as a result of International Maritime Organization (IMO) restrictions on cleaner fuel (Cullinane and Bergqvist, 2014).

However, there aren't many studies that focus on the variables that influence or obstruct the green port strategy in different countries, especially in developing ones where the tension between protecting the environment and promoting economic growth is increasingly obvious. This study tries to pinpoint the key elements affecting ports' future decisions to adopt more environmentally friendly port models. Research on the elements that support and obstruct the development of green ports might be useful to the government and port authorities. The port authority may be aware of the advantages of a green port through drivers, but the government creates legislation to aid ports in the process of implementing sustainability requirements through obstacles. Additionally, this study is the first to apply a quantitative method to look at the factors impacting the adoption of green ports, surveying 10 main ports in Vietnam. The Vietnamese government's Green Port Development Scheme states that ports must voluntarily adopt sustainability standards by 2025 and must do so by 2030. Finding these elements will therefore advance the body of knowledge on green ports while also having theoretical merit.

2. Literature review

2.1. Green port

The negative effects of port activity on port stakeholders and a long-term and green port development plan include the production of air pollution, oil pollution, excessive noise, health problems, and ecological hazards (Xie et al., 2022). The key issue in ecological port is striking a balance between the impact on the environment and business interests. A green

port, also known as a green port, is therefore recommended in a number of studies as a viable remedy for this problem (Lam and Yap, 2019). According to Vellinga (2011), a green port (also known as a green port) is one where the port authority, working with port users, proactively designs and conducts, relying on an economically sustainable strategic plan, working with natural philosophy, and engaging stakeholders. Starting from a long-term goal on the location in which it is positioned and from its position of privilege within the supply chain, this port authority ensures development that anticipates the future. While Nikitakos (2012) backed the idea that a zero-emission green port would produce all of its renewable energy sources (RES), such wind turbines or a small solar park, to balance any energy consumed in managing the port's activities. In addition, according to Zis (2019), a green port is one that has either made an investment in new machinery with improved environmental performance or has developed a strategy to reduce emissions, energy consumption in operations, and water pollution, or is otherwise making an effort to become a "greener" port. The three bottom lines of economic development, social well-being, and environmental protection should be controlled and balanced by green ports, according to Lam and Yap (2019). Green ports actively incorporate climate change mitigation and adaptation measures into their policies and objectives.

2.2. Criteria for green port

The major objectives of sustainability at ports are to increase profitability, decrease CO2 emissions, find eco-friendly ways to deliver logistical services, save the environment, and use less natural resources for the benefit of future generations. The idea of sustainability, according to a research by Hiranandani (2014), is bringing mindfulness to the port business and pressing it to embrace new procedures and capabilities. Some requirements require ports to cut back on their production of greenhouse gases, air pollution, and other waste (Abood, 2007). For instance, some academics recommend the variables in Table 1 below.

A port's sustainable performance may be assessed using a range of metrics, but little has changed with regard to them over the previous three decades. Most academicians (Chin and Low, 2010; Yap and Lam, 2013) have concentrated on controlling air, noise, and water pollution. However, some studies (Chiu et al., 2014; Park and Yeo, 2012) have placed a high focus on the use of alternative energy sources and training for green port performance as important aspects in environmental conservation.

Table 1. Criteria of green port

	Criteria	Previous studies
1	Air pollution management	Bailey and Solomon (2004); Berechman and Tseng (2012); Chen and Pak (2017); Chin and Low (2010); Fitzgerald et al. (2011); Gupta et al. (2005); Papaefthimiou et al. (2017); da Silva Portugal et al. (2011); Tzannatos (2010); Wiegmans and Louw (2011).
2	Noise pollution management	Chen and Pak (2017); Lirn et al. (2013); da Silva Portugal et al. (2011); Wiegmans and Louw (2011).

	Criteria	Previous studies
3	Water pollution management	Chin and Low (2010); Frankel (1987); Peris-Mora et al. (2005); Wiegmans and Louw (2011); Yap and Lam (2013).
4	Solid waste pollution management	Gupta et al. (2005); Wenning et al. (2007); Zonn (2005).
5	Energy usage	Chen and Pak (2017); Gilman (2003); Lirn et al. (2013); Park and Yeo (2012); Peng et al. (2020); Zhen et al. (2022).
6	Natural ecosystem	Fernandez (2007); Rietkerk et al. (2002).
7	Training on sustainable port	Chiu et al. (2014); Gilman (2003).

In order to empower the personnel at the implementation level, port sustainability often necessitates considerable expenditures in new equipment, complex operating processes, and specialist training programs. Given the deteriorating profitability of the ports, port officials are worried that these issues would result in increased expenses (Chen and Pak, 2017). The adoption of green ports clearly needs strong motivators, especially in emerging countries where environmental preservation and economic expansion are at odds. Although these factors affect whether ports decide to invest or not, little research has been done on them. If these concepts are not grasped, the port greening process will take longer. So, the purpose of the next section is to look at the factors affecting how the green port plan is implemented.

2.3. The key factors of green port

2.3.1. Environmental regulations

In order to protect the port environment and lower the risk of pollution, environmental regulations include international treaties and national policies (Cullinane and Cullinane, 2013; Zis et al., 2014). The International Maritime Organization (IMO) was founded by the United Nations in 1948 to develop and enforce a comprehensive regulatory framework for shipping. It is now in charge of issues with security at sea, the environment, legislation, technological collaboration, shipping efficiency, and more. The majority of states, including Vietnam, have ratified the IMO accords. At the same time, a number of environmental rules have been established in the European Union, mostly concentrating on air pollution, biodiversity, water and marine ecosystems, soil, and other components that would lessen environmental threats. All EU members must abide by European directives. Each country must ratify the European regulation within a reasonable time limit and implement it into its legal system. Each nation creates its own environmental policy in accordance with its commitments and demands. The nation's environmental policy combines the tasks and goals of the nation (Puig et al., 2022). For instance, by the year 2030, the Vietnamese government wants all ports to operate in accordance with green port standards. Based on the justification given above, we predict that environmental laws will have a favorable influence on the implementation of green port policies (Tseng and Pilcher, 2019; Zis et al., 2014).

Hypothesis 1: Environmental regulations positively influence the implementation of green ports.

2.3.2. Lack of technical advancement

The application of cutting-edge technology in environmentally friendly ship and port infrastructure is referred to as technical development. A number of cutting-edge technologies, including as seawater filters, cold ironing technology, alternative energy sources, and monitoring systems, have been suggested for use at green ports in Cullinane and Cullinane's (2013) research. Seawater is pumped, for instance, in the cramped scrubber of a ship. The scrubber receives ship exhaust gas, which interacts with saltwater there. According to Andreasen and Mayer (2007), when SO₂ comes in contact with seawater, a rapid and efficient reaction takes place, changing the SO₂ and Calcium Carbonate (CaCO₃) in the saltwater to CO₂ and Calcium Sulphate (gypsum), an essential component of ordinary seawater. Additionally, cold ironing is the technique of feeding a ship with electricity from the land rather than using its auxiliary engines while it is berthed. The capacity to shut down all engines is the result of this. Only when on-shore power is generated from renewable energy sources can cold ironing minimize greenhouse gas emissions (Green et al., 2008). In truth, it has been found that cold ironing reduces overall transportation-related greenhouse gas emissions by less than 0.5% (Frey, 2008). In addition, the development of advanced monitoring systems has made it feasible to locate potential pollution sources and provide timely pollution control actions (Tseng and Pilcher, 2019). In order to reduce emissions into the environment and support environmental goals, complementary or alternative energy sources including wind, solar, and biofuels can be used (Cullinane & Cullinane, 2013).

Finally, technology may be used to rethink operational procedures in order to develop sustainable business models and manage contaminated trash more successfully in ports and on ships (Di Vaio et al., 2022a). In the cruise industry's efforts to achieve the United Nations 2030 Agenda for sustainable development through sustainable trash management, for instance, Di Vaio et al. (2022a) highlighted the importance of digital technology. Digitalization and modern technology allow for decreased atmospheric emissions, but more crucially, more efficient resource use, which encourages a shift in the business model to achieve sustainable development goals (Di Vaio et al., 2022b).

According to previous research (Chang and Wang 2012; Cullinane and Cullinane 2013; Di Vaio et al. 2022a), advanced technology is essential for the port to meet its sustainability goals. However, the technology utilized in green ports poses a big problem for ports today. Most ports in underdeveloped countries have outdated equipment, which is bad for the environment. Access to new technologies will be challenging in the short future. Equipment that requires electricity, onshore power sources, and systems for creating alternative energy all require considerable capital investments over protracted periods of time. Because of this lack of current technology, executing a green port plan in poor countries would be quite difficult. We hypothesized that:

Hypothesis 2: Lack of technical advancement negatively influences the implementation of green ports.

2.3.3. Cooperation of involved parties (shipping lines, transportation companies)

Cheon (2016), Denktas-Sakar and Karatas-Cetin (2012), and Lam et al. (2013) are only a few of the many published papers, both inside and beyond the scope of this study, that acknowledge the challenge of changing ports toward sustainability and the necessity to incorporate a wide variety of stakeholders. There are three types of green port environmental issues, according to the OECD (2011): 1) Ship emissions; 2) Port operations; and 3) Hinterland traffic. Key causes of air pollution brought on by shipping include sulfur oxides (SO_x), nitrogen oxides (NO_x), and particulate matter, all of which have an impact on local and regional air pollution. Additionally, the physical and emotional health of dockworkers as well as residents in coastal regions might be negatively impacted by noise from ship auxiliary engines during laytime. Due to the enormous number of cars that go to and from ports, pollution and traffic are the key issues from an inland perspective (Gonzalez-Aregall et al., 2018). The Association of Southeast Asian Nations highlighted one of the major barriers to the sustainable growth of ports in Asia as poor coordination with shipping companies and other supply chain partners (Roh et al., 2016; Zheng; Zheng and Luo, 2021).

Numerous earlier studies have demonstrated that the coordinated effort by multiple parties to lessen the pressure on the port authority will make it easier to implement the green port strategy (Bergqvist and Egels-Zandén, 2012; Luo et al., 2022). As one of the primary ways that ports can reduce emissions from vessels (Winnes), shipping companies can support a more environmentally friendly port strategy by implementing more environmentally friendly ships, such as propulsion upgrades and auxiliary engine retrofits (Eide et al., 2009; Geng et al., 2016), or by reducing their speed in the port area (Ahl et al., 2017). Second, some significant solutions for the inland transportation system are provided to reduce air pollution, noise, traffic accidents, and congestion by developing an intermodal rail and road infrastructure and encouraging shippers to transfer their goods by rail to and from ports (Bergqvist and Egels-Zandén, 2012). With the help of the parties concerned, the implementation of the green port will be more successful. We expect that:

Hypothesis 3: Cooperation of involved parties positively influence the implementation of green ports.

2.3.4. Reputation

A corporate reputation is a stakeholder's total assessment of a firm over time, according to Gotsi and Wilson (2001). This assessment is based on the stakeholder's first-hand interactions with the business, any other means of symbolism and communication that conveys information about the firm's behavior, and/or a comparison with those of other major competitors. According to Flanagan and O'Shaughnessy (2005), a solid corporate reputation has become an important part of many organizations' competitive strategy. Positive corporate reputation is a source of strategic competitive advantage since it increases a company's ability to join markets, broaden its market reach, and offer value to consumers (Miles and Covin, 2000). Reputation is a fundamental intangible asset, according to Feldman et al. (2014), since it offers a business a long-term competitive advantage and affects stakeholders' purchasing decisions (Rindova et al., 2005).

Container shipping is a transnational industry with fierce rivalry in the shipping industry. Businesses may become more competitive by using environmentally friendly shipping services (Yang et al., 2013). Shrivastava (1995) outlined how environmental management might increase a company's competitive advantages by reducing the negative environmental effects of its activities. Success in environmental management might improve a business's standing and create new opportunities for it to grow its capabilities (Hansmann and Kroeger, 2001).

The port's reputation might stem from its perceived environmental friendliness in this regard. As a result, in addition to improving their reputation, these ecologically friendly ports may also experience sustainable development and economic rewards. According to earlier research (Lam and Li, 2019; Notteboom, 1997), among the many essential elements influencing port choice, qualitative aspects including port reputation, security, and customs handling quality are critical considerations that should not be disregarded. The reputation of a green port is the most important component in luring and keeping clients that respect sustainability, according to Chan et al. (2012). In order to draw clients, green port managers might use their reputation as a marketing weapon, according to Lam and Li's (2019) research. We predicted that the adoption of green ports would be favourably impacted by their reputation based on the considerable benefits outlined above.

Hypothesis 4: Reputation positively influences the implementation of green ports.

2.3.5. Economic incentives

Economic incentives are the use of monetary rewards to persuade port users to adopt environmentally friendly operating procedures and reduce adverse effects on the port environment (Blinge, 2014; Tseng and Pilcher, 2019). The Port Authority of Rotterdam awarded participating ships with a certificate and a "Green award," according to study by Mellin and Rydhed (2011). The "Green Award Certificate," which has more standards, and the "Basic Certificate," which has less requirements, are the two levels of certification. Ship owners with these credentials will pay less for port and pilotage services in about 23 ports across the world. In the "carrot and stick" approach, penalties are commonly used to increase shipowner compliance. The penalty might be a fine or an increase in the cost of using port services.

In order to promote port sustainability, the government should use financial incentives to motivate the port authority to reduce emissions and environmental degradation. The interviews conducted for Blinge's (2014) study brought to light the significance of applying both positive and negative incentives (carrots and sticks) while building sustainable corridors. Some experts believe that a voluntary program with the possibility for a green label would be beneficial and provide holders an advantage over competitors. Therefore, we anticipate that:

Hypothesis 5: Economic incentives positively influence the implementation of green ports.

2.3.6. Awareness of green port

The knowledge of green ports includes both economic and environmental knowledge (Chang, 2013), as well as knowledge of new technology with improved environmental performance or of strategies to reduce emissions, energy consumption in their operations, and

water pollution (Zis, 2019). Additionally, it is important to introduce a grasp of the rules and incentives for green ports. It is believed that voluntariness in the construction of green ports would be significantly impacted by a thorough understanding of green ports. Port authorities will be more motivated to keep their social obligations if they can perceive the economic, environmental, social, and sustainable advantages of the green port. We hypothesize that:

Hypothesis 6: Awareness of green port positively influence the implementation of green ports.

3. Results

According to Pavlic et al. (2014), the primary objective of the green port is to continually minimize negative environmental consequences without compromising economic growth. In order to use resources and alternative sources of energy efficiently, green ports must spend heavily in technical innovation. But there aren't many studies that especially target emerging countries, where there are rising tensions between economic development and environmental conservation, in the academic literature. Numerous insights into the variables influencing the implementation of green ports are provided by our research. The findings of this study are particularly noteworthy since they originate from a large sample of managers who are representative of container ports, with a focus on Vietnam.

The international MARPOL 73/78/97 convention is the most pertinent and comprehensive legislative intervention on environmental issues in the port and shipping industry. Major international organizations have continuously and deeply intervened in the MARPOL 73/78/97 international convention over time by producing amendments, regulations, standards, and proposal of guidelines (Di Vaio and Varriale, 2018). Examples of these organizations include the International Maritime Organization (IMO) and the Marine Environment Protection Committee (MEPC). A number of conventions addressing environmental pollution issues have been introduced by the International Maritime Organization (IMO), a special agency of the United Nations tasked with regulating the security and safety of shipping. Recently, the IMO has placed a strong emphasis on preventing marine pollution by ships. The main treaty, known as Marpol 73, was the International treaty for the Prevention of Pollution from Ships, which superseded the International Convention for the Prevention of Marine Oil Water Pollution. In reaction to the environmental disasters caused by oil tankers in the late 1970s, the 1978 and 1997 protocols—signed at the TSPP (Tanker Safety Pollution Prevention) Conference—revised this agreement. The purpose of the MARPOL 73/78/97 convention is to stop ships from unintentionally or purposefully discharging pollutants into the ocean. The rules for draining spent oil, sewage, and trash are governed by six annexes that went into force between 1983 and 2005.

According to Lam and Notteboom (2014), environmental regulation is now the most efficient and targeted technique for the control and prevention of pollution. The government can put the demands of environmental regulation into practice by developing market-oriented incentive programs, such as the collection of pollution fines and environmental taxes, or command-and-control policies, such as the passage of local laws and regulations.

Our study's findings are consistent with those of other studies (Deng et al., 2022; Lam and Notteboom, 2014; Di Vaio and Varriale, 2018) in that environmental legislation positively affects the implementation of the green port. The reason for this is that, although not being a favorite, laws also entail consequences for non-compliance, which have evolved into a potent motivation for the adoption of sustainable standards. In the context of Europe, there are several legislations that address environmental issues pertaining to the port industry. The European Union (EU, Brussels, Belgium) has set regulations in place that can help establish environmentally conscious and green ports and supports audacious worldwide projects addressing tools to avert global warming (for example, by easing the transition to a low-carbon economy). Initiatives taken by the EU in this field (Directives 2012/33/EU, 2012/27/EU, 2014/94/EC; EU Regulation No. 2015/575) aim to ensure environmental sustainability in the seaport industry.

Innovation and technological advancements can help to lower greenhouse gas emissions (Bergqvist and Monios, 2019; Wiegmans and Geerlings, 2010). In ports, for instance, ship emissions are a growing problem, particularly for SO_x, NO_x, and PM that have an impact on the health of the surrounding population. Cold ironing methods are mostly employed in ports to cut down on ship emissions. Instead of utilizing their auxiliary generators (cold ironing, onshore power supply, or OPS) to generate power for hoteling, ships at berth connect to shore-side electricity (SSE). According to Chang and Wang (2012), employing an onshore power supply system might reduce CO₂ and PM emissions by 39.4% and 57.16 percent, respectively. If all ports in Europe switched to shore power in 2020, Winkel et al. (2016) estimated that health costs could be reduced by 2.94 billion USD and carbon emissions might be reduced by 800,000 tonnes. According to the findings of our study, a major impediment to the implementation of green ports in developing nations is a lack of advanced technology. For instance, the port greening process will take longer due to a shortage of electrical equipment, renewable energy sources, and monitoring software. The expensive setup and maintenance of the equipment used to make up for the lack of contemporary technology is one potential explanation for this.

Identifying the collaborative role of port stakeholders in the development of green ports in particular and other firms in general is one of the study's findings that are consistent with previous research (Bergqvist and Monios, 2019). For instance, a variety of methods are already being used by shipping firms to diminish their environmental impact, mostly in order to abide with international standards that demand that they reduce emissions. They can use an onshore power system, alternative fuels (MGO, LNG), slow down to 12nm when near the port, stop dumping ballast water at ports, or other cooperative behaviors that are thought to promote the attainment of the green port strategy.

Our research also focuses on how a port's reputation affects how it is implemented. In order to improve a company's brand equity and reputation, corporate social responsibility (CSR) is essential (Ahmad et al., 2022). Contrary to what we expected, the port's green image value had no impact on the performance of the green port. One explanation might be that consumers don't care about corporate social responsibility. Environmental issues usually receive less attention than economic ones, especially in underdeveloped countries.

Economic incentives appear to be an efficient way to persuade port authorities to adopt a green port strategy in order to promote the use of cutting-edge environmental technologies, improved resource management, and energy-efficient transportation. The restriction of access to transportation infrastructure, financial incentives like tax breaks, and price drops for energy are typical examples (see, for instance, Bergqvist and Egels-Zandén (2012). Our findings supported prior study (Lalla-Ruiz et al., 2019) in that economic incentives have a large and favorable impact on the implementation of green ports.

Port enterprises should raise their level of environmental protection awareness, actively build green ports, and occupy a favorable competitive position in green port transportation through the use of sustainable technology innovation, such as raising the utilization rate of environmental protection equipment and reducing pollution control costs. Additionally, staff employees can attend training sessions to better understand the role that sustainability plays in protecting both the environment and human health. Contrary to what we had anticipated, port authorities' implementation of green ports is unaffected by the fact that they are aware of them. One argument is that the government's necessity for their implementation, rather than the port authority's choice, is what has led to the public's knowledge of green ports.

4. Discussion and Conclusion

This study makes several contributions to theory and research. First, our research defined what a "green port" is broadly speaking and showed how it supports environmental protection without impeding port expansion (Zis, 2019). Therefore, green ports actively include climate change mitigation and adaptation approaches into their strategy and objectives in order to manage and balance the three bottom lines of economic development, social well-being, and environmental preservation (Lam and Yap, 2019). Our study has compiled the standards for a green port in order to reduce the port's detrimental environmental effects while preserving financial viability. Some of the criteria that have been mentioned in prior studies include staff training, alternative energy usage, noise pollution management, solid waste management, water pollution management, and solid waste management (Chen and Pak, 2017; Chin and Low, 2010; Peris-Mora et al., 2005). Our research offers a thorough knowledge of environmentally friendly ports, emphasizing not only the elimination of pollution sources but also the improvement of management and staff sustainability awareness. This important theoretical addition has improved the literature on green ports.

Our research also contributes to the body of knowledge already available on green ports by exploring the critical elements affecting the implementation of green ports. Our results support other research' conclusions that environmental laws play a crucial role in the development of green ports (Cullinane and Cullinane, 2013; Tseng and Pilcher, 2019). Our study supports both the effect of national policy on environmental protection through mandatory guidelines and norms as well as the significance of international accords. National laws and regulations have a substantial influence on port compliance with environmental criteria, even though the International Marine Organization (IMO) is the primary marine transport authority. The relevance of regulations at the national and

international levels is better understood as a result of implementing sustainability requirements to ports. National rules appear to be a substantial addition to international legislation on the preservation of the marine environment.

Although prior research had demonstrated the role of technological leverage in reducing environmental impact and supporting the construction of green ports, our study demonstrates that the absence of modern technology will adversely affect the implementation of green ports, which are widely used in developing countries (Cullinane and Cullinane, 2013; Di Vaio et al., 2022a). As a result of reduced atmospheric emissions and more effective resource usage brought about by digitalization and new technologies, business models are changing in order to support sustainable development goals. The results of our study have improved the theoretical foundation for green ports in developing countries where the demand for sustainable development and the availability of current technology for implementation are still in conflict. This study shows how important cutting-edge technology are for implementing a green port model, but it also emphasizes how out of reach these technologies are in underdeveloped countries. This adds to the corpus of research regarding obstacles to constructing viable ports in underdeveloped nations.

One of the major achievements of this study is the realization of the significance of stakeholder cooperation in the development of green ports. According to our research, stakeholders like shipping lines (which use light fuels, don't discharge ballast water at ports, and reduce speed in RSZ), transport companies (which use vehicles that adhere to Euro 4 standards), and others must work together for the green port strategy to be successful. Our understanding of the elements that contribute to successful sustainability requirements at ports is improved by this result. Stakeholders may drastically reduce emissions and aid in environmental conservation by changing their former behaviors. This result, which has important ramifications for port authorities managing stakeholder activities, affects the success of a green port. According to other studies (Tseng and Pilcher, 2019), our study supports the notion that financial incentives from the government could have a favorable impact on the development of green ports. Governments should continue to be mindful of the significant implications of our results if they want to extensively promote green ports. Ports are urged to implement sustainability standards by providing financial incentives such as lower taxes, cheaper energy, or loans with low interest rates.

Port administrations may also employ a variety of other possible policies to encourage stakeholder cooperation in the development of sustainable ports. Using an annual environmental excellence awards program, port authorities may select the most environmentally friendly businesses across a variety of operational areas, and they may then reward them with a bonus or a reduction in port fees. Peak and off-peak hours may be less frequent as a result of effective demand-based pricing regulations, which would reduce fuel waste and air pollution. It is suggested that a pollution tax, flexible port pricing, and a "carrot and stick" strategy may induce port operators to adopt more ecologically friendly operating procedures (such as low sulfur fuel, shore power, clear trucks, clear ballast, water recycling, solar energy, etc.).

Abstract

Climate change is one of the biggest environmental challenges facing humanity in the 21st century. Vietnam is not an exception of these perils; the consequences of climate change are extremely serious and are existential risks for Vietnam's sustainable development. In the context that climate change is a new risk with a large impact scale, if insurance industry does not proactively adapt, it will face losses significantly and lower opportunities for future growth. More seriously, risk management role of insurance industry could be threatened. The article identifies current climate risk insurance products in Vietnam industry and suggest recommendation for better practice.

Keywords: *Disaster Risk, Climate Change, Insurance*

1. Introduction

According to United Nations Framework Convention on Climate Change, "Climate change is a change in physical or biological environment that causes significant adverse effects on the composition, resilience or reproductive capacity of natural ecosystems, the operation of socio-economic systems or to human health and welfare".

The main manifestations of climate change that can be recognized globally including: Increase in atmospheric temperature - Global warming, Rainfall change, Sea level rise due to melting of polar ice caps and mountainous regions, natural disasters and extreme weather events (heat, cold, storm, flood, drought, etc.) occurring with increased frequency, irregularity, and possibly intensity.

According to Stern Review (2010), a sea level rise of 20-80 cm (due to a 3 - 4 degree Celsius increase in Earth's temperature) will put an additional 7-300 million people at risk of flooding every year. If there are no adaptation measures, the number of populations in 136 major cities around the world experiencing hurricanes will increase from 40 million (2005) to 150 million (2070s), and property damage could increase from \$3 trillion to \$35 trillion. UNEP FI report (2006) estimates that losses from weather events will increase by 6% per year and double globally every 12 years on average.

World Bank (2007) assessed that Vietnam is one of the five countries seriously affected by climate change and sea level rise, in which Red River Delta and Mekong River Delta will be most affected. If the sea level rises by 1.0m, it will imperil nearly 10% of the population; 10.9% of urban area; approximately 35% of Mekong Delta population; over 9%

of Red River Delta population; nearly 9% of central coastal population and about 7% of Ho Chi Minh City population; over 4% of the railway system; over 9% of the national highway system and about 12% of the provincial road. Moreover, GDP loss is approximately 10.2%

However, so far, despite facing many risks and challenges related to climate risks, Vietnamese insurers have not paid attention to develop exclusive product lines dealing with these growing risks. Additionally, there is almost no research on related products and insurance services which cope with disaster and climate risks.

2. Method

The article used the method of synthesis and statistical analysis. Data sources are taken from VCCI, Stern Review, ADB reports for summarizing and analysis. The article describes disaster and climate risks facing by insurance industry and then suggest some solutions to improve market performance to stakeholders.

3. Results

3.1. Vietnamese Enterprises' current status of participating in insurance to prevent disaster risks and climate change

In addition to taking specific actions to handle disaster risks and climate change's impact, businesses can reduce losses by purchasing insurance products. In VCCI survey (2020), 44.5% of 10,356 respondents are using a certain insurance line to prevent risks related to disaster risks and climate change. The proportion of FDI enterprises currently obtaining an insurance product is 62.2%, significantly higher than the rate of private enterprises (41.3%).

As demonstrate in Figure 1, the most commonly purchased insurance product is property, machinery and cargo insurance. 55% of FDI enterprises and 33% of private enterprises obtained this product. The proportion of enterprises obtaining interruption insurance products was relatively low, with only 4% of FDI enterprises and 2% of private enterprises. About 10% of FDI enterprises and 9% of private enterprises join other insurance policies.

Figure 1. Categorizing businesses in terms of operation years and purchased insurance products

Source: VCCI

Besides, Mekong Delta enterorises have highest demand for insurance products. Meanwhile, Central Highlands enterprises have a lower demand than other regions. The possibility of obtaining insurance is positively correlated with the size of enterprises. Regardless of capital size or labor size, the analysis shows that as the size of the enterprise increases, the possibility of joining insurance policy increases.

Figure 2. Rating insurance products' usefulness by enterprise clients

Source: VCCI

As insurance clients for disaster risks and climate change, these firms rate usefulness of insurance product as 4 levels, including: 1) Very useful; 2) Relatively useful; 3) Less useful; and 4) Unhelpful. The result implies that the majority of respondents, especially FDI enterprises highly value the usefulness of purchased insurance products. Overall, 86% of businesses highly rates purchased insurance lines whilst only 4% rates these unhelpfully.

3.2. Solutions to handle disaster and climate risks

Insured losses related to climate risks have tended to increase since 1990, leading increase in insurance deman which creates a potential market. In order to control loss payment and manage climate risk effectively, insurers improve and develop new products to limit losses and exploit hidden markets.. Global insurance industry has also taken action to seize opportunities and deal with these new challenges. Specifically:

Insurers' active risks management strategies

Since introducing new insurance lines, insurers have been shifting from being passive to proactive in responding to new risks. From suffering negative impacts and indemnifying costly claims caused by climate change, insurers has taken proactive steps, setting the foundation for new business opportunities. Leading insurers identify climate change as their top priority in long-term business strategy.

In competitive market, insurers tend to launch comprehensive insurance products and packages to meet consumers' requirements. At the beginning of the 1930s, Japan and the United States introduced agricultural insurance. By 1950, this insurance line become

more popular. Since the 1990s, insurance products such as flood insurance, green building insurance were also introduced in the market and gradually developed, accompanied by improvements in product design and add - on services for customers. Pioneering in providing these products are international insurers/brokers such as Fireman Fund, AON, Lloyd's...

Via researching on and developing climate risk policies, insurers have gradually developed risk assessment and analysis techniques, applied appropriate insurance terms, and provided new climate - related products and services, improved indemnity services; strengthened methods of loss reduction, shared knowledge and experience, thereby, enhance the ability to:

- Risk management through coping and adaptation measures and tools;
- Taking advantage of new business opportunities and sustainable investments;
- Assisting clients in risk management and loss reduction via knowledge sharing, experience and consulting services;
- Changing operating activities environmentally friendly.

Integrating new terms and services into traditional insurance policies

One of the solutions to adapt to climate risks is that adding more regulations and terms to limit losses when risks occur in high-risk areas. Instead of offering high premiums or not providing services, companies take a new approach: adding mandatory conditions that policyholders need to meet if they want to obtain insurance. In Australia and Japan, the government has issued a set of rules for residential buildings which specify their structures, the size of used materials, especially in areas that are often subjected to high damages caused by climate change such as earthquakes, tornadoes, tsunamis, etc. Thus, insurers make regulations that force customers in these high-risk areas to comply with above construction regulations when purchasing their products. In some cases, to limit losses, insurance companies can also add new terms to screen customers, target low-risk groups and satisfy provisions on limiting losses.

Enhancing customer service/ loss limitation consulting

When offer customers different types of insurance, especially product for assets with CO2 emissions such as cars, sales agent helps customers compare car models according to safety and environmentally friendly criteria. In addition to serving customers' new requirements, this service also indirectly adjusts their consumption behavior, which contributes to raising their awareness about environmental protection. Furthermore, when accessing company's website and submitting vehicle's technical information and usage level, clients support insurers calculating the amount of greenhouse gases emitted by this vehicle and then deciding on claim payment (AIG Insurance). Customers can voluntarily enroll in carbon credit program offered by AIG by paying a small fee (corresponding to vehicle emissions); 100% of the raised fund will be used for the carbon credit program, serving afforestation projects within 100 years.

Investing in early warning technologies of natural disasters and climate change

Understanding the characteristics and levels of risk and damage of natural disasters caused by climate change is especially essential for minimizing these damages. Increasing public awareness of climate change creates opportunities for insurers on supplying prevention limiting losses services, developing natural disaster risk assessment technologies from previous experiences and obtained knowledge. The British company Norwich Union (Aviva) has run an electronic flood map in the UK, thereby contributing to increase people's awareness of the risk to their property. The company also develops models of flood-resistant houses which are predicted to significantly reduce flood damage by using flood warning and flood control systems. Other insurance - related firms such as IAG, Munich Re, Swiss Re, Lloyd's have also developed disaster risk identification, warning tools and develop online maps for customers and insurers to refer to.

4. Discussion and conclusion

The barriers of Vietnam insurers in climate change adaptation strategies are still significant for the following reasons:

Significant Risk

Insurers are likely to go bankrupt due to payment for multiple disaster losses. Therefore, when risks are not geographically classified, insurers are suddenly faced with significant losses that cannot be offset by premium revenue. For example, insurance companies in river basins, coastal areas, and reclaimed land need to recognize the correlation between floods. Insurance companies will charge higher premiums for areas with higher systemic risk to compensate for the possibility of bankruptcy, ensuring solvency. One feature of climate risk is the low probability but high impact of insured events. This makes it difficult to cover losses and to provide adequate capital for subsequent losses.

However, these issues can be gradually resolved and their impact constantly reduced due to flexible nature of the insurance industry: Premiums and policies can be adjusted annually, thus contributing to limiting risks for insurers

Asymmetric information: Adverse selection and moral hazards

Concerns about problems caused by adverse selection will affect the expansion climate risk insurance. Adverse selection is a phenomenon in which policyholders focus their selection on higher-risk subjects to insure. Therefore, insurer will have to bear higher loss when the premium is calculated based on average probability of expected loss. The cause of adverse selection is asymmetric information between insurers and policyholders. This problem is more serious when customers can identify their risk levels and characteristics while insurance companies have difficulty in differentiating good risk and bad risk groups. If asymmetric information is excluded, insurance company only needs to charge higher premiums on high-risk subjects. Adverse selection leads to high premiums because insurers protect themselves against risk exposure.

Asymmetric information between insurers and policyholders also leads to moral hazards. The insured is often less careful, more prepared for risks which the insurance

company cannot control, so loss possibility will be higher. Moral hazards may increase when individuals are already covered under climate risk policy. Nonetheless, insureds' moral hazard is a secondary issue in climate risk insurance as they cannot control when insured event occurs (i.e. the probability of loss), although they can control the extent of damage during and after floods, droughts, epidemics...

Public awareness of climate change

Because additional terms related to climate change risks or "green" insurance are voluntary choices of customers. If customers are not aware of the role and importance in their consumption behavior, insurance enterprises will face difficulties in market development. Moreover, the phenomenon of unfair competition between insurers may appear. In same policy, but insurer only needs to remove green insurance clause to be able to reduce fees and attract customers. Therefore, business thinking and customer awareness are two factors that significantly affect the existence and development of green insurance products.

Product design

Firstly, in order to be insurable risk, its loss frequency and severity need to correspond to estimated benefits. It will be difficult to actualize these two conditions for climate risk policies because risks such as floods, droughts, etc. consequences of climate change often occur with low frequency and high severity. Loss calculation would be highly challenging without large-scale loss data systems which need to be gathered over a long period. The uncertainty associated with climate risk is substantial. The impact of climate change on the frequency of insured risks (such as droughts, floods, epidemics, etc.) is also an uncertain factor. Therefore, the solution to this problem is risk sharing between insurers and the government. However, in order to develop global insurance market which plays a role as an effective economic and environmental tool, it is necessary to develop new strategies.

Secondly, insurance firms must determine risk - based rates. This can be a major challenge due to uncertainty risk, adverse selection, moral hazard and systemic risk.

Difficulty in risk assessment

Difficulty in assessing risk possibility and estimating losses makes it difficult for insurers to offer appropriate premiums and manage risks. Practical experience shows that the more uncertain risk frequency and loss severity are, the higher the proposed premium is. Premium for climate risks will be higher than other risks, such as fire, explosion, machine breakdown, etc. although expected loss may be similar. The uncertainty factor associated with climate risks is significant because there is currently very few scientific information and data collected over a sufficiently long period of time to be able to identify risks characteristics (such as frequency, severity, location...). Insurers can use disaster models to study losses caused by these disasters, however, this approach is not yet able to completely solve uncertain factor.

From aboved issues, some recommendations are suggested as follow:

The government needs to take legal measures, including: providing a legal framework for business activities, administrative measures such as regulation of investment portfolio,

licensing of establishment...; financial measures such as tax and fee incentives, price subsidies to attract participation public and insurance enterprises participating in climate risk insurance market. Furthermore, the government create a favorable legal framework issue preferential policies for businesses to deploy this insurance line. Granting exemption and reduction of taxes and other payables to state budget for insurers providing climate change-adapted products.

Integrating regulations on compulsory purchase of climate risk insurance in some cases such as bank and mortgage loans. It can be upgraded to a general coercive regulation, especially in high-risk areas such as coastal areas, central coast, Mekong Delta... Promulgating regulations, framework decrees, documents guiding the implementation of climate risk products which specifies roles, responsibilities and coordination mechanism among stakeholders.

Additionally, the government also needs to create a legal corridor for insurers to coordinate with scientists to develop a database system which collect loss information on national scale continuously. Simultaneously, it also stipulates a mechanism for sharing information between stakeholders.

In long term, when new risk insurance have become popular, the government should support insurers to overcome difficulties in compensation when climate change risks cause great losses. In addition to facilitating the development of private insurance products, the government can also create public insurance to guarantee households in the event of large-scale and simultaneous losses. Instead of providing comprehensive coverage, the government can join reinsurance market to overcome difficulties caused by interrelationship between posed risks. The strength of governments playing the reinsurer role is that they can spread the risk to entire population as well as future generations. The cooperation between the Government and insurers is absolutely necessary, contributing to strengthening enterprises' financial capacity in dealing with correlated risks or large-scale damage, then builds trust in the insured

Insurers can organize specialized seminars, set up research groups, mobilize articles or organize research contests in specialized journals to gradually disseminate knowledge about green insurance. The exchange and cooperation in scientific research and training also contribute to raising enterprise awareness.

Insurance industry also needs to invest in developing infrastructure and information systems to create an appropriate premium schedule. Based on the mechanism and legal corridor promulgated by the government, insurers actively set up a database system on climate risks as well as customer database system for centralized management and serve as a basis for charging and controlling risks. These data systems need to be collected for a long time because climate risks are long-term accumulation process as a basis for scientists and researchers identify risk frequency and loss severity, overcome limitations of uncertainties in climate risk policy

In order to handle moral hazard, insurers may apply deductibles or coinsurance. An appropriate deductible will be an incentive for individuals to take loss-limiting measures.

One advantage of applying deductibles is to reduce transaction costs because only insureds with losses above the deductible are compensated. This provision is especially useful for climate risk policies. Under coinsurance terms, clients will be motivated to limit losses and take precautions due to shared risks

Scientists also play a supporting role in providing information, cooperating with insurers in risk assessment, loss assessment, completing information sharing mechanism and ensuring effective application of scientific research, especially in risk management.

As consumer is those who have full access to information on climate change, the sense of proactive self-protection and property is enhanced, the trend of green consumption is encouraged, they make the demand for insurance products with reasonably design and good service quality.

EVALUATE THE POTENTIAL FOR THE DEVELOPMENT OF SOME CIRCULAR BUSINESS MODELS FOR PLASTIC PACKAGING IN URBAN AREAS IN DEVELOPING ECONOMIES

MA. Trinh Thi Tuyet Dung

tuyetdungirsd@gmail.com

Institute of Regional Sustainable Development,

Vietnam Academy of Social Sciences, Vietnam

Dr. Vu Kim Chi

chivk.ivides@vnu.edu.vn

Institute of Vietnamese Studies and Development Science, Vietnam

Abstract

Prior to the global issues of climate change, environmental pollution, and ecosystem degradation, the world is aiming to achieve net-zero emissions by 2050. Many countries have implemented circular economy strategies and received participation from businesses in implementing business models. Depending on the scale of the enterprise and the circular business models, the implementation can vary. This article identifies some circular business models for plastic packaging in Hanoi. Through the SWOT analysis of strengths, weaknesses, opportunities, and challenges, this article evaluates the potential for the development of circular business models for plastic packaging in the future. The research results will be a useful reference for managers and businesses in developing new plastic economy business models in urban areas in developing countries like Vietnam.

Keywords: *circular economy model, plastic packaging*

1. Introduction

Plastic pollution contributes significantly to greenhouse gas emissions and other global environmental issues such as ecosystem degradation. According to calculations, in 2018, total emissions from the plastic industry accounted for 3-4% of the total global greenhouse gas emissions. In addition, plastic pollution in the ocean affects around 700 species of marine life (Gall & Thompson, 2015). Research has shown that the majority of plastic is used in packaging production, accounting for 36% of plastic production or 144 million tons in 2018 (UNEP, 2018). This is the source of pollution in the ocean and at open dumpsites. In Vietnam, plastic packaging waste accounts for about 70% of total plastic waste in landfills and beaches (WB, 2021). Therefore, global efforts are shifting towards a new plastic economy, which applies circular economic strategies in the plastic packaging industry.

One of the solutions that has been previously mentioned in research is the transition to a circular economy (CE). Implementing CE for the four main material industries, including plastics, has a positive contribution to the goal of achieving net-zero emissions by 2050 (EMF, 2018). Therefore, circular economy strategies and models are being applied in many industries such as agriculture, construction, and waste management. In the group of

service and retail businesses, some business models are regaining attention as they align with the circular economy framework.

In a developing economy like Vietnam, financial resources and consumer habits have a significant impact on business strategies. As the global trend shifts towards a circular economy, Vietnam is also introducing many new environmental policies such as Law No. 72, which considers circular economy as a necessary model for achieving sustainable development and net-zero emissions. Moreover, Vietnam's National Action Plan on circular economy also prioritizes circular business models.

The circular business model is the concrete implementation of circular economic strategies for plastic materials. EMF provided suggestions for implementing circular business strategies in the new plastic economy model prior to 2020 (EMF, 2018), which includes topics such as packaging design and implementing reuse and refill models. Accordingly, this model takes several forms, including (i) returnable, where the container is owned and cleaned by a company (or group of companies), and (ii) refillable, where the container is owned by the consumer after the initial purchase and then filled with refill products (at home) or taken to a station to be refilled while in transit (Ellen MacArthur Foundation, 2019; Greenwood et al., 2020). Implementing circular economic strategies has led to the emergence of circular business models in practice. The circular business model itself is an indispensable part of the circular system.

Regarding the concept, the circular business model is the theoretical basis for how an organization creates, distributes, and captures value within closed-loop resource cycles (Mentink, 2014). Thus, the circular business model goes hand in hand with the way a business distributes its products and implements resource loops. Subsequently, many other authors have specifically defined the concept of circular business by specifying principles (Bocken et al., 2022; Linder & Williander, 2017), detail strategies of the R framework (Geissdoerfer et al., 2018). Lahti and colleagues are more interested in the aspect of organizing stakeholders (Lahti et al., 2018) to achieve economic, social and environmental benefits. Therefore, the circular business model is a business model that cycles, extends, intensifies and/or dematerializes material and energy loops to reduce resource inputs and leakages of waste and emissions from the organization's system. Including 4 solutions that are cycling, extending, intensifying and dematerialising (Geissdoerfer et al., 2020). This concept has described in an easily understandable way about the circular business model according to the principles of the circular economy that EMF has put forward.

Faced with issues of climate change, ecosystem function degradation, and environmental pollution, the research on the circular business model in plastic packaging has increased over the past five years, directly and through implementing the EPR mechanism. Circular business models for plastic packaging have achieved the benefits of the circular economy principles that EMF has put forward, including reducing resource exploitation and natural materials, extending product life cycles, and limiting waste generation and negative environmental impacts (EMF, 2018). These business models have been implemented in many multinational corporations worldwide as well as in Vietnam. The

business trend is shifting to forms of leasing packaging products, applying reuse support platforms, and filling globally.

The development of a business model is closely related to the feasibility, desire, and ability to exist of business models. Experience in fast-moving consumer goods shows that five success factors are identified, including brand and retailer partnerships, consumer participation, operational effectiveness, model profitability (Bocken et al., 2022). Meanwhile, the main barrier for businesses to implement the model is cost (Bocken et al., 2022), usually the input cost when investing in a business model.

In urban areas of developing economies such as Vietnam, resource-saving models and waste reduction are common. However, research has only described the models and communicated more about the implementation results. Classifying and evaluating systematically with SWOT is still a gap. Therefore, there is a need for an article that specifically analyzes the circular business models for plastic packaging in the case study in Vietnam. From there, strengths, weaknesses, opportunities, and challenges in developing this business model can be clearly seen. The content will be considered on the ability to expand the scale over time and space.

2. Method

This study uses a typical case study method to investigate circular business models in Hanoi. A total of 04 typical models were selected for the study, which is appropriate for circular business models for plastic packaging. In-depth interviews were conducted with business owners or project owners, focusing on general operational information of the models and their representatives' assessment of the model's development potential.

To analyze these typical models, the study used the SWOT analysis technique. SWOT was first developed at Harvard Business School in the 1950s in classic studies (Benzaghta et al., 2021). This analysis method has gradually been widely used in many fields with the main purpose of making strategic decisions. Previous studies have also shown that SWOT is a common technique and is suitable for classical studies. It is also a suitable tool for organizing a company's position assessment in the market (Dyson, 2004). By evaluating the strengths and weaknesses of the model, opportunities and challenges can be identified for future model development. Model development is evaluated based on scalability and long-term development capability. A SWOT analysis diagram is created with the framework below.

3. Results

This section describes the typical circular business models for plastic packaging. The roles of related parties and the financial benefits they receive will be outlined.

3.1. Typical Circular Business Models for Plastic Packagin

Circular business models for plastic packaging are based on the flexible combination of the R strategies of the circular economy proposed by Potting (2015). "Reuse" means using the same product again or multiple times (by different users or owners) while it remains in good condition and is managed sufficiently to meet the product's initial function (Morseletto, 2020). In practice, there are many types of models, which are often flexibly combined with other R strategies such as "refill" and "return". Refill is a part of reuse. However, the concept of refill focuses on the product being traded, while reuse focuses more on the packaging of the traded product. The purpose of both refill and reuse is to increase the product's life cycle, limit waste, and extend its lifespan. Similarly, reuse and return are concepts that are more concerned with consumer behavior. This is how they treat packaging after use.

3.1.1. Refill Station

This is a Refill Station where refilling is conducted. Currently, it is implemented in three cities in Vietnam, including Hoi An, Quang Ninh, and Hanoi. The Refill Station offers a full range of environmentally friendly product solutions according to the 5R model (Reduce, Re-use, Recycle, Repair, Refuse) (Lại Văn Mạnh et al., 2022). Refilling is the only activity carried out at the station, thus encouraging consumers to bring their used packaging for reuse. The Refill Station provides both in-store and mobile (moving) product sales services.

Figure 2. Refill Station

This model involves the participation of the sales business, consumers, and cosmetic businesses. However, the active and core role comes from the sales business. The involvement of the cosmetic business is less clear. Since this model exists in two forms: mobile sales at traditional markets and fixed sales at stores, the customer group is also more diverse and divided into two types. One is the group of customers who regularly purchase products and reuse plastic packaging at the store. Consumers in this group have a higher level of awareness and practice of environmentally friendly behavior. Meanwhile, the group of consumers at traditional markets has a more spontaneous nature and the model also has a high level of performance and experimentation.

3.1.2. The automated cosmetics vending machine model (ATM refill)

The automated cosmetics vending machine is a combination of R strategies, including refill, return, and reuse. The machine can provide recycled packaging, usually recycled plastic bottles and various Unilever cosmetics products. First-time buyers can purchase the plastic container separately before buying the product. The cost of purchasing the container is calculated separately from the cost of purchasing the product. Therefore, consumers have the option of bringing their own plastic bottle to refill, which can be done from the first purchase. Consumers have the option to reuse a plastic bottle that has been recycled from their previous purchase, for refilling the product they wish to buy on their second purchase.

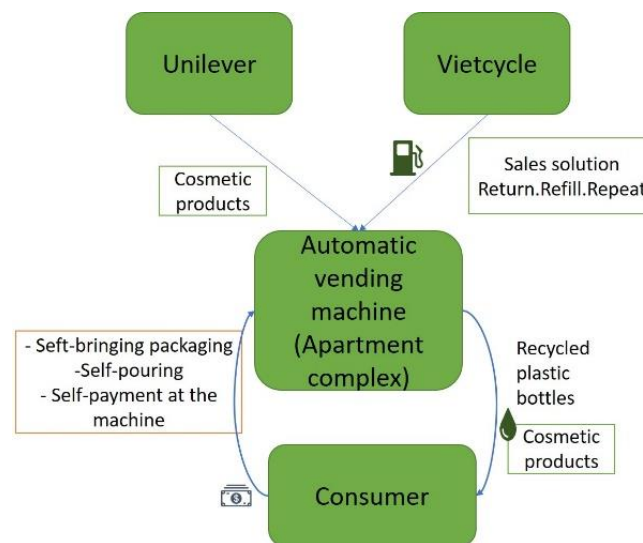

Figure 3. ATM-refill - Vietcyle

In this model, there is active and positive involvement of recycling businesses, who also operate the sales points. In addition, there is a close link between the recycling company and the Unilever brand.

3.1.3. Model of product packaging return at retail stores - Showroom

In small-scale cosmetic retail businesses, the model of exchanging packaging for gifts or points is being implemented. The plastic bottles are reused for the cosmetic products sold by the retail businesses. Consumers receive gifts based on the number of product packaging they bring in to exchange. This model maximizes the infrastructure of the product distribution process. In this model, the manufacturing, business and retailing companies and consumers are directly involved, with the retail businesses taking an active role.

3.1.4. Model of selling products and packaging

This model is widely used in fast-consumption drink businesses such as bottled water. Consumers pay for both the packaging and the product (packaged drink) on their first purchase. After consuming the product, consumers return the packaging to exchange it for other packaging and pay for the new product that comes in the new packaging. This model

is commonly used for drink businesses such as beer, bottled water and mineral water. The active role in this model is played by the product-selling businesses. Examples of this business model include distributing 20-liter bottled water and beer kegs.

3.1.5. Plastic packaging collection model - gift exchange

The plastic packaging collection model for gift exchange is popular among environmental groups. Although it is not a profit-driven business model, there are increasingly more groups collecting plastic packaging and offering gift exchanges. The development of this model is a precursor to the expansion of the responsibility of large-scale manufacturers. Currently, the active role belongs to environmental groups, with weak links mainly to informal collectors, some of whom are linked to recycling companies. This model can be developed into a business where environmental groups are linked to plastic waste-generating companies, recycling companies, and recovery companies. Among them, plastic waste-generating companies carry out environmental responsibility to society through the amount of plastic collected by environmental groups and transferred to the recycling company. The exchange mechanism is in the form of plastic credits.

3.2. Analysis of the development potential of circular business models for plastic packaging

The development potential of these models depends on factors that affect the implementation and practice of circular business models. These factors include policy, the degree of benefits to stakeholders, awareness of environmental benefits, and trends towards green or sustainable consumption.

Regarding the market and policies, these models are suitable for the trends in the market and circular economic development policies in Vietnam. The country is taking action to institutionalize the implementation of circular business models and expand the responsibility of manufacturers in plastic waste recycling.

In terms of the degree of benefits to stakeholders in implementing circular business models, consumers benefit directly from reduced costs of purchasing multiple packaging. Communities benefit from reduced plastic packaging waste after products are used and distributed in the market. Enterprises benefit by demonstrating responsibility for collecting and recycling plastic for society. However, the direct financial benefits of these models vary among enterprises. Not all business models result in cost reductions for companies. Only in the case of model 5, financial benefits are unclear. Maintaining the operation of model 5 currently requires additional funding. The mandatory implementation of the EPR mechanism is a driving force for promoting circular business models in the future.

Awareness of the environmental benefits for consumers and the trend towards green or sustainable consumption are both strengths that enable the circular business models for plastic packaging to develop in the present and future. Consumers' awareness has changed significantly, but there still exists a gap between awareness and behavior. The challenge is to make sustainable behavior become the norm accepted by the community.

The development potential of circular business models is analyzed based on criteria such as the level of benefits for stakeholders, popularity, stakeholders' awareness, policies and plans, and Extended Producer Responsibility (EPR)

Table 1. Model 1- Gift-for-shell model-Comem

<p>Strength</p> <ul style="list-style-type: none"> - Convenient and available at business retail locations - Both consumers and businesses benefit financially 	<p>Weak</p> <ul style="list-style-type: none"> - The amount collected is low and insignificant compared to the amount sold. - Customers have to keep enough packaging to exchange for gifts.
<p>Opportunity</p> <ul style="list-style-type: none"> - Build a green and socially responsible business brand - Create a community of consumers who are connected to the product. A loyal customer base 	<p>Theart</p> <ul style="list-style-type: none"> - Create a habit of cleaning, storing, collecting, and returning packaging after use - Ensure the profitability of the business

Table 2. Model 2 - ATM-refill - vietcycle

<p>Strength</p> <ul style="list-style-type: none"> - Reducing the amount of packaging waste released into the environment. - Aligning with the government's policies to encourage sustainable business models 	<p>Weak</p> <ul style="list-style-type: none"> - Investment in infrastructure and technology for the automated vending machines. - Higher investment costs from the business side. - Risk of leakage of cosmetic and personal care products during the production process. The quality of the product may be reduced if not properly packaged and sealed. - No connection with the retail supermarket system yet.
<p>Opportunity</p> <ul style="list-style-type: none"> - Expanding to more retail points - areas with low to medium collection rates. - Providing products for smart consumer market. - Scaling and replicating the business model. 	<p>Theart</p> <ul style="list-style-type: none"> - Ensure the benefits of both the cosmetics business and the business implementing the model. - Ensure the quality of cosmetics products, production techniques, and large-scale packaging. - Expand partnerships and manage vending machines.

Table 3. Model 3- Plastic waste collection and reward model

<p>Strength</p> <ul style="list-style-type: none"> - Supported by individuals and environmentally conscious communities - Collecting clean plastic - a secondary resource for the next production process - In line with consumer trends and waste sorting policies 	<p>Weak</p> <ul style="list-style-type: none"> - Irregular collection according to a predetermined schedule. - Customers have to keep enough packaging until they can exchange them for gifts. - Lack of financial resources to operate, frequently calling for support
<p>Opportunity</p> <ul style="list-style-type: none"> - Create a group of environmentally responsible, waste-sorting consumers. - Develop and expand in the future to form a plastic collection-only business. 	<p>Theart</p> <ul style="list-style-type: none"> - Ensuring the profitability of the business operation - Collaborating with plastic manufacturing and recycling businesses.

4. Discussion and conclusion

Refill-reuse business models used to be popular in economies facing shortages of goods and consumer products in the past decade. In the 90s, refill-reuse was widely implemented in beverage products such as beer, wine, and soft drinks in developing cities in Vietnam. This business model was not only applied in large companies but also existed in small-scale production and trading households. At the enterprise level, the implementation model followed a system of agents and retail points. The common practice was that consumers bought products (usually liquid, such as bottled beer), paid a deposit, and when returning the empty bottles, the retail agents refunded the deposit. However, due to the convenience trend in consumption and the explosion of goods in the past 20 years, this sales model has gradually narrowed.

The analysis of the models in this study shows that the implementation of business models between recycling companies, trading companies, and manufacturing companies has laid the foundation for the initial development of the business model. However, to facilitate management and expand the model, it is necessary to link with the regional management of stations/points. Based on the experience of the refill-reuse model in the UK, it is recommended to combine it with the retail supermarket system. The implementation of this specific circular business model in enterprises will be encouraged by the policy changes in Vietnam, which have a breakthrough character in circular economic strategies to achieve a net-zero emissions goal by 2050.

Along with the strong development of IoT technology and AI artificial intelligence, the circular business model for plastic packaging is increasingly growing. With the main trend of using more modern technology and techniques. In addition, the development of circular business models for plastic packaging in developing countries will follow the trend of selective learning from existing models in the world.

The development, dissemination, and expansion of this business model require encouraging policies and participation of all relevant parties. Policies should focus on exploiting opportunities and limiting the challenges of developing the circular business model for plastic packaging. Specifically, issues that need further research and discussion include:

First, perfecting the EPR mechanism for plastic companies in responsibility for recovery, recycling, and carbon credit implementation. Research on the responsibility of consumers regarding plastic credit or conversion into an ecological footprint.

Second, enforcing environmental policies on the use and production of plastic packaging, such as the implementation of regulations on the production of biodegradable packaging materials, reducing the use of single-use plastic packaging, and promoting the use of reusable packaging.

This study clarifies the operation of the model as well as the involvement of stakeholders. Using the SWOT analysis technique, it identified opportunities and challenges for developing circular business models for plastic packaging. This complements the use of SWOT analysis in research. However, to increase the reliability of this method when researching policies to encourage circular business models, the PESTLE technique could be combined. Furthermore, future studies on circular business models in urban areas of developing countries could continue to analyze consumer intentions for refill-reuse behaviors. This can lead to mechanisms and solutions to break down barriers, stimulate the motivation and behavior intentions of consumers. In addition to policies on EPR mechanisms and environmental funds being researched, the feasibility of plastic credits and consumers' willingness to pay for pollution fees can also be studied. This research direction will contribute positively to expanding and developing circular business models for plastic packaging.

UTILIZATION OF NATURAL CAPITAL IN CIRCULAR ECONOMY: SOLUTIONS FOR SUSTAINABLE ECONOMIC DEVELOPMENT

Dr. Nguyen Thi Hien Oanh

nthoanh@sgu.edu.vn

Saigon University, Ho Chi Minh City, Vietnam

Abstract

With the complicated developments of climate change and the risk of depletion of natural resources, most countries in the world consider the development of a green economy as an indispensable step in their development strategy. Economic development, including Vietnam. Using natural capital in the circular economy, looking to the future, a closed system that does not waste natural resources.

Keywords: *Natural capital, green economy, circular economy.*

1. Introduction

The green economy will be a new direction for the economy in the future. Both developing and developed countries have recognized that the transition to a green economy is an opportunity to increase employment and develop markets for goods and services. Meanwhile, developing countries are focusing on solutions to poverty-related issues and sustainable development planning, in which a circular economy is a solution: (i). *The reason for conducting this research:* Faced with the increasingly complex and rapidly increasing predictions of climate change, together with the serious destruction of natural resources, resulting in negative impacts on the environment and society, integrating green growth goals into economic development is essential for every country; (ii). *Determine the research issues;* Efficient utilization of natural resources in a circular economy; (iii). *The main focus of the research is to address the following issues.* Utilizing natural resources in a circular economy is an economic model that combines sustainable economic growth with sustainable development through a harmonious and tight integration between them; (iv). *Introduction of research contributions:* Natural resources are necessary for the prosperity of humankind; Circular economy - green economy for sustainable development.

2. Theoretical Framework and Method

Research overview: (1). “Blue ocean economy - Issues and Approaches for Vietnam” (2020) by the author Nguyen Chu Hoi. The content clarifies the theoretical basis, approach, and objectives of implementing the blue ocean economy, the reality of blue ocean economy development in the world with some good practices and practical experiences on blue ocean economy development; (2). The Waste-Free World (2022) by Ron Gonen. The content highlights how the extractive-production-disposal economic system is depleting natural resources and putting the planet on high alert. But things don't necessarily have to happen

this way. The Waste-Free World presents a circular economy model, aiming for the future, a closed-loop system that does not waste natural resources.

Theoretical basis: Brown Growth, Brown Economy, Green Growth, and Green Economy mean the terms that are increasingly used nowadays. Countries around the world have undergone a transition from brown growth to green growth, which contributes to making production and consumption more sustainable, improving quality of life, and reducing the impacts of climate change. Brown growth describes economic development that is largely based on fossil fuels and does not take into account the negative externalities from economic production and consumption on the environment. On the other hand, green growth is seen as a transition to a cleaner energy system, more efficient use of energy, and better management of natural resources.

Research methodology: This article employs document analysis to provide an overview of the relationship between natural capital utilization in the circular economy and green economic development.

3. Results

3.1. Natural capital for human prosperity

3.1.1. Natural Capital

Natural capital plays a critically important role in human prosperity, serving as the foundation for sustainable socio-economic development and bringing prosperity to individuals and nations. However, until now, there is still no complete consensus on the concepts of natural capital and natural asset. The differences in these concepts often reflect differences in the purpose, scale, and target of exploitation, use, and management of natural resources on land and in the ocean.

- *Capital* is a concept in economics that refers to the assets, whether tangible or intangible, that can be used to generate income, goods, or services for human life and development” [12].

- *Natural capital* refers to the assets or resources that are naturally occurring, such as natural resources (organisms, ecosystems, minerals, land, water, rivers, lakes, oceans, climate, etc.), which human beings can utilize to generate income, goods, and services” [7]. Some other studies suggest that natural capital is a set of assets of the ecosystem (value of services and functions), combined with other types of capital (social capital, human capital) to create essential services for economic-social development and support human well-being” (Costanza R. & Daly H.E, 1992, 37). In other words, natural capital refers to all the values and benefits derived from natural resources or the natural supply of seafood, including geological resources, land, air, water, and the entire terrestrial, marine, and oceanic biosphere.

- *Natural capital (or resources)* is all types of natural resources (living and non-living), natural components (material and non-material), and ecosystems. According to James K. Boyce, natural resources only become natural capital when humans have the right to access their benefits (own them), such as clean water, clean air, and common natural

heritage, ... (James K. B (2001). Ecosystem services provide benefits such as food, water, cultural and recreational values, pollination, climate regulation, air quality regulation, and disease control (Costanza R (1997). Therefore, to ensure that these services continue to support human welfare and livelihoods, the aforementioned natural assets and capital need to be conserved and sustained in the long term. In reality, humans have lost many natural resources, but they can also regenerate them to varying degrees depending on the form of resource ownership, human perception, and effort.

From a relational perspective, natural capital includes physical capital and ecosystem capital, as well as natural resources with various types of goods and services.

Natural capital: comprising physical capital and ecological capital

- Physical capital: Commodities: Minerals, elements of the earth, fossil fuels, ...; Services: Energy supply, transportation means, ...

- Natural capital: Commodities: Products that are derived from the structure and function of ecosystems; Commodities: Support services, provisioning services, regulating services, cultural services.

3.1.2. Natural capital - the foundation of economic and social development

Economists have described the natural environment, including the marine environment, as natural capital since the early 1970s. However, recently, governments of countries and private sectors have started to use the concept of natural capital in the decision-making process for development plans. The advantages of a natural capital-based approach are that in addition to natural resources, the natural environment is considered a valuable asset that needs to be managed, valued (monetized), accounted for, and examined for the factors that may affect the natural capital's ability to provide goods and services in the future.

For national strategies, natural capital creates "static advantages", while mechanisms and policies create "dynamic advantages". *Static advantages* (the inherent potential of nature) are vulnerable to depletion and damage from natural disasters, climate change, and human activities, therefore it needs to be conserved; *dynamic advantages* need to be flexible, and adaptable, and create openness to awaken the potential of nature in a way that is efficient and sustainable. The dynamic advantage and the static advantage always support each other, interacting with each other in the process of development, and are two sides of an issue in efficiently exploiting and sustainably using natural resources.

The ecosystem services such as water resources, food, and energy are the pillars of economic development, but the contribution of these services has not been adequately evaluated in the accounts of many countries. It can be said that goods and services provided by natural resources are of significant value to human life and development, as well as to the nation. In reality, however, these assets are often viewed as "free assets" and are not economically valued appropriately, leading to unsustainable management, wasteful exploitation and use, and a lack of concern for the long-term benefits of natural assets for future generations. While if we have not fully understood the role of natural assets and their

true value (as recognized), we can easily answer the remaining questions such as: how to use natural assets efficiently and how their use affects human welfare, ...

In practice, there is a connection between biodiversity, ecosystem services, human health, and socio-economic development. The ecosystem services provide food, water, air, cultural and spiritual values, as well as support climate regulation and disease control. Biodiversity provides basic human needs for food and nutrition, maintains the sustainability of the environment and water resources, and promotes human health; creates direct benefits to address food insecurity and malnutrition; builds sustainable and efficient production systems for agriculture and aquaculture; enhances resilience to shocks and crises caused by climate change and natural disasters; improves rural economy and household livelihoods; supports to reduce external factors affecting land degradation, water cycles, and genetic diversity.

Most economic development plans and projects, from micro to macro scale, directly or indirectly impact the environment and natural resources due to the close linkages between ecosystems and economic activities. Along with economic growth comes the depletion of natural resources and the ability to sustain ecosystem services. The economic value of ecosystem services can be estimated, and the present value of ecosystem services is a fundamental part of natural capital. Natural assets such as forests, lakes, wetlands, river basins, oceans, and seas are important components of natural capital at the ecosystem level, playing a crucial role in maintaining the stability of the water cycle for agriculture and subsistence benefits; reducing the impact of climate change through carbon cycle management; the fertility of the soil and its value for agriculture; local climate conditions for habitat safety; aquatic protein, etc. These are all the decisive factors for green economic development. Integrating natural capital, especially ecosystem services, into the framework of sustainable development is necessary to ensure that development policies do not undermine efforts to maintain biodiversity and ecosystem services.

3.1.3. Natural capital - the foundation for energy, food, and water security

Various studies have demonstrated the importance of natural capital for ensuring energy, food, and water security, including oceans and poverty reduction for nations [10].

Many reports have also pointed out that Vietnam is one of the countries most affected by climate change, with the Mekong Delta being one of the three deltas in the world most vulnerable to sea level rise. According to the General Statistics Office of Vietnam, in the Mekong Delta region, up to 62.17% of the population is engaged in agriculture, forestry, and fisheries, and about 75% of the livelihoods of people in the region depend on agriculture, aquaculture, and partly on catching natural aquatic animals. Therefore, the expected impacts of climate change according to scenarios have highlighted a real threat to agricultural production in the Mekong Delta region and directly threaten the livelihoods of the people in this area (Nguyen Chu Hoi, 2020, 20).

3.1.4. The trends of climate change and the role of natural capital in supporting key economic sectors and adapting to climate change

- Trends of climate change in the world and Vietnam

Humanity is exceeding the carrying capacity of the natural environment and accruing ecological debts that future generations will be unable to repay. Climate change causes extreme weather phenomena, and sea level rise, and impacts various economic and social sectors, as well as different regions and territories. The more vulnerable objects are to climate change, the less resistant they are to its impacts. Climate change forces us to think in a completely different way about the interdependence between human beings. Regardless of any other aspects, humanity still shares a common existence on a planet - Earth. The bonds that connect communities across the planet are spanning regions, countries, and generations. No nation, no matter how large or small, can remain indifferent to the fate of other lands, or ignore the consequences of taken actions today that will affect future generations. In the past, the world had gone through four ice ages alternating with periods of melting, causing the surface temperature of the Earth to fluctuate, usually between 5-7 °C, with some places in the Northern Hemisphere experiencing up to 10-15 °C. That is the phenomenon of 'geo zone moving', corresponding to the periods of 'sea transgression, sea regression' caused by melting or freezing of ice. The last sea transgression period, named Frandrian, occurred about 20,000 years ago and the last ice age occurred about 6,000 years ago (Nguyen Chu Hoi, 2020, 47).

According to the climate change scenarios in 2009, 2012, and 2016 approved by the Prime Minister, by the end of the 21st century, the average temperature in our country will increase by about 2-3 °C, the annual and rainy season rainfall will increase, while the dry season rainfall will decrease, and the sea level may rise around from 75cm to 1m compared to the period of 1980-1999. Since 1951, the average annual temperature in Vietnam has increased by 0.7 °C. The average annual rainfall has not increased significantly over different periods and regions: there have been periods of increase and periods of decrease.

Over the past 50 years, at the Cua Ong and Hon Dau stations, the average sea level has risen by about 20cm, in line with the global trend. A recent abnormal climate phenomenon in the context of global climate change is the prolonged and severe cold caused by a cold air mass, which has caused significant damage to production activities. Recently, the number of strong typhoons has increased, the typhoon trajectory has gradually shifted to lower latitudes, and the typhoon season ends earlier. Many typhoons have irregular paths, and their trajectories are more chaotic, making them difficult to predict.

By 2100, it is projected that the sea level will rise by about 1 meter and the temperature will increase by about 3 °C. According to estimates, if the sea level rises by 1 meter, 10% of Vietnam's population will be directly affected, GDP will be reduced by about 10% and about 40,000 km² of Vietnam's coastal plain will be flooded annually. If sea levels rise by 90cm in 2070, about 50,000 hectares in the Red River Delta, 1.5-2 million hectares in the Mekong Delta, and around 400,000 hectares of mangroves and marshy areas in the South would be inundated (Nguyen Chu Hoi, 2020, 48).

- The role of natural capital in supporting key economic sectors and in adapting to climate change

Natural capital supports the development of key economic sectors such as agriculture, fisheries, forestry, tourism, and mining, ... Natural capital also supports industries and services such as tourism, which relies heavily on natural landscapes and particularly on eco-tourism associated with the conservation of nature, the sea, islands, and coastal areas.

Natural capital, especially ecosystems, provides a variety of services to humans and the economy, from provisioning services such as water and food to regulating services such as local climate regulation (Millennium E.A (2005)).

Protecting and restoring degraded ecosystems is an effective, cost-effective, and sustainable approach to offsetting the impacts of climate change and negative human impacts, particularly in the field of environmental economics. Strengthening ecosystem management will contribute to enhancing their self-healing capacity as well as increasing resilience to the impacts of climate change; protecting carbon sinks and contributing to climate change adaptation strategies. Climate change is increasingly impacting humans through increasing pressures on the integrity, functioning, and ecosystem services. Failures to invest in ecosystem protection that provides water and food services and protects critical coastal areas will jeopardize the livelihoods and millions of human lives (UNEP (2011)). Along with the growing awareness of the ecosystem's role in adapting to climate change is also increasing.

To rapidly reduce the number of atmospheric pollutants, scientists suggest that ecosystems in general and coastal ecosystems specifically (such as mangroves, seagrasses, and coastal wetlands) can absorb and store large amounts of CO₂ and are considered "carbon sinks" that help mitigate climate change. In principle, all living organisms, including animals, plants, algae, and bacteria, contain carbon, making them function as carbon sinks. If a green tree is still alive, it will absorb and store carbon, but once it is cut down and turned into firewood, the carbon will be released and emitted back into the atmosphere as CO₂.

3.1.5. The economy as an ecosystem

One of the far-sighted figures, among whom is Herman Daly. He popularized a viewpoint that he called a "steady-state economy," and as he wrote, this "is not a static economy but a dynamic, constantly regenerative one". He was inspired after reading the book *Silent Spring*. He recounted that at that time he was amazed to realize that "if you sit down, take out a piece of paper, and draw a small picture depicting the economy as a subset of a larger ecosystem", you will see that all economic growth is achieved at the expense of the ecosystem. He said that we were foolish to think that the human economy is an artificial structure that exists independently of nature, while in fact, it is completely dependent on the natural world and needs to learn a lot from natural processes. Next, he advocated for a radical shift from the growth-oriented economic model - and the cults of GDP - to a sustainable economic model and became one of the main advocates for sustainable development.

The question here is: How can we have a new economy that conserves, or even better, replenishes the natural world, while still being a prosperous economy that allows us to continue to improve the quality of life - including the quality of life of the developing world? In the search for answers, economists have turned to the field of ecology, and Daly had a huge impact as one of the founders of the new field of ecological economics, which laid the foundation for the concept of circularity.

3.2. Circular economy - green economy

3.2.1. From sustainable development to Regeneration

What is a circular economy? It is an economy that invests in advanced technologies related to material science, product design, recycling, and manufacturing, leading to a "closed-loop" system without waste where resources are not wasted. The products are made using clean, renewable energy sources and are locally produced; the materials used in production are sustainable, reusable, and recyclable materials, or biodegradable materials that do not cause environmental pollution and are being strongly developed today. The products are designed for long-term durability - not to quickly lose their value - and can be reused or repaired. Money is no longer wasted and the lives of all species are no longer destroyed by excessive dependence on natural resource exploitation and disposal of products in landfills. The design and production processes are optimized towards harmony with nature, with the product users, and with the communities in which they live.

The transition to applying circular methods to production, distribution, consumption, and the reuse of products and materials for healing our planet, also creates significant economic opportunities. Entrepreneurs with a spirit of innovation and creativity can use circular solutions to build businesses that have the potential to bring about significant social changes and rapid growth. Big corporations can reduce activities such as raw material procurement, product packaging, and transportation cost while satisfying customers with progressive, environmentally friendly perspectives. From a consumer perspective, we can save significantly by purchasing products that have a longer lifespan, can be upgraded and repaired when broken, and only subscribe to the services we desire from a product instead of paying a large sum to fully own the product. The circular economy ensures that consumers, consumer goods companies, and urban residents own an economy that operates for their benefit. It eliminates the need for a hundred billion dollars in costs for resource extraction and disposal of wasteful products that we have been paying for over the past seven decades. Equally important, it prevents the practice of stealing land and oceans from environmental polluters who loudly proclaim that such actions are necessary for economic development and growth. In a circular economy, fraudulent behavior is not encouraged. The factors here are practical effort, hard work, transparency, and innovative creativity.

Although a transition to a circular economy may seem infeasible due to the benefits of companies deeply ingrained in the extractive and wasteful use of resources. In fact, it is precisely the reasons for transitioning to a circular economy that is the strongest driving force behind the increasing adoption of this concept. Another important factor that is equally

important as the government's role is to encourage innovative activities in companies to produce products and services that have the potential to bring about change - of course, accompanied by the demand of consumers for these products and services.

At present, businesses have strong incentives to transition to a circular economy model. The reason here is not only because pioneering brands on this journey have achieved impressive achievements in both profit and consumer loyalty, but also because of the increasingly frequent appearance of effects caused by climate change. More and more companies are facing challenges in their supply chains, as the depletion trend of natural resources continues to drive up production costs. Not only that, they also struggle to cope with increasingly frequent natural disasters, from floods to water scarcity, from wildfires to rising sea levels. In addition, brands are increasingly aware that the public will hold them accountable for environmentally destructive practices as well as tactics to undermine the development of environmental protection solutions they implement.

3.2.2. The unique superiority of the circular economy model

In his role as founder and CEO of Closed Loop Partners, the first investment firm to prioritize mission-driven investments in circular solutions. The concept of the circular economy first appeared in the 1960s, but it is only recently that it has become a topic of interest for business leaders, financial investors, and key figures in non-governmental organizations. The driving force behind it is a group of entrepreneurs actively participating in designing products and services based on the circular economy model. The reason here is that these people have realized that the circular economy is a superior approach that helps them generate profits, while also having the potential to bring about change in the fight against climate change.

Walter Stahel, a Swiss architect and one of the thought leaders who founded the concept of a circular economy, has played a significant role in promoting the superiority of a closed-loop system. He founded the Product-Life Institute to implement circular production activities. Through these non-profit organizations, he has advised businesses, governments, and non-governmental organizations for many decades. He also played a critical role in setting out the core operating principles for the circular production model.

+ *Diminution*: Continuously reduce the demand for natural resources, waste generation, environmental damage, and greenhouse gas emissions.

+ *Reuse*: Prioritizing durability in product development, so that products and packaging can be transferred to new users without the need for refurbishment (or with only minor adjustments).

+ *Remanufacturing*: Repairing, refurbishing, and remanufacturing.

+ *Restoration*: Designing products that can easily disassemble parts and reuse materials within them, while also developing a "reverse logistics" process, is a model in which manufacturers and retailers reclaim sold products to refurbish and resell or recycle.

+ *Regeneration*: Utilize only renewable energy, apply regenerative production methods, and construct buildings that can self-supply resources (Nguyen Chu Hoi (2020), 23-24).

3.2.3. From sustainable development to Regeneration

In the climate change debate, the burning of fossil fuels is a topic that attracts a lot of attention, leading to important advances in this area. The process of converting energy from electricity and wind power is happening rapidly and plays a crucial role. But according to estimates, two-thirds of greenhouse gas emissions are directly attributable to the extraction of natural resources, production, and disposal of consumer goods.

The linear economy system, which is wasteful and harmful to the environment, was highly developed in the 20th century to enrich companies by exploiting an increasing amount of natural resources. For instance, extracting oil to manufacture plastic products, mining ores to produce metals, and logging trees to make paper, without taking responsibility for the damage they cause to the environment. They also disregard the public interest to earn profits by producing products that are not optimally durable, making these products quickly become obsolete or discarded after a single use. This behavior creates pressure that forces companies to continue to extract more natural resources to produce new products.

Consumers may thoughtlessly dispose of products along with their packaging after a single use rather than repairing, reusing, or recycling them, which has been deeply ingrained in the public subconscious through advertising campaigns. Advertising is also responsible for encouraging the habit of discarding products that are still in good use in favor of "upgrading products" or more attractive products. Taxpayers are often unaware that the companies responsible for these actions have been shifting the costs onto us for a long time. Many of the most serious violators, such as fossil fuel companies, have quietly lobbied for and received a hundred billion dollars in federal subsidies. The public is unaware that they have spent billions of dollars in taxes to subsidize the development and growth of industries that profit from the take-make-waste model of the economy.

There is no reason for us to continue paying for the exploitation of natural resources every time whenever we use a product or pay for the disposal of that product after it has been used. For the past 75 years, we have been deceived by paying for unnecessary costs, while the natural resources of land, air, and water that we jointly own are being seriously degraded and destroyed.

The damages that the Earth and societies living on the planet have to bear are becoming increasingly shocking. The pace of climate change is happening even faster than all previous predictions. Droughts are occurring more frequently and severely, contributing to the increase in the number of widespread forest fires. The large fires not only release a significant amount of carbon into the atmosphere but also greatly reduce the carbon absorption capacity of the burnt forests and destroy the habitat of hundreds of thousands of people each year. The tropical rainforests, which are currently the most powerful carbon sinks, are being degraded at an estimated rate of 80,000 square kilometers per year. The studies have shown that both the record-breaking heatwave in Europe in the summer of 2020 and the torrential rains brought by Hurricane Imelda, which caused severe flooding in Texas in September 2020, were intensified by climate change. According to the United Nations

estimation, by 2025, two-thirds of the world's population will be affected by the water scarcity caused by climate change (Ron. G, 2022, 15).

Many communities around the world have already witnessed the severe consequences of climate change, especially in poor regions and among indigenous peoples. According to Fourth National Climate Change Assessment Report released by the US federal government in 2018, people living in poorer areas of the United States are the most vulnerable to the impacts of pollution and property damage caused by extreme weather events. Polluting factories are often concentrated in impoverished areas, which are mostly home to minority communities. For example, according to information from Fortune Magazine, the West Louisville area of Louisville city in the state of Kentucky, where 80% of the population is black with an average income of \$25,000, is the place with the worst air quality among all medium-sized cities in the US. The air here is heavily polluted due to the presence of 56 regular emissions-producing factories. On average, residents in the West Louisville area have a life expectancy of about 12.5 years shorter than white residents living in wealthier areas of the same city (Ron. G, 2022, 15).

3.2.4. Sustainable development process

Looking back in history, before 1970, international efforts to protect the environment were still very fragmented, sporadic, and ineffective, with little impact on national and community levels. In the development process of the world, each region and country has faced many common pressing issues, including: as the economy grows, the scarcity of non-renewable resources such as fuels and energy sources increases, the natural environment is increasingly destroyed, the ecological balance is disrupted, and natural disasters are becoming increasingly devastating. The divergence between economic growth and social progress and development is a problem that plagues many regions and countries. Economic growth alone does not guarantee social progress and equality. Furthermore, economic growth often exacerbates the wealth gap, leading to social instability. Therefore, in the process of development, it is necessary to regulate a harmonious balance (harmonious development) between economic growth and ensuring social security and environmental protection. In other words, sustainable development has become a pressing demand for humanity and a global concern (Pham Thi Thanh Binh (2018).

The limits of growth prompted nearly 100 countries to come together at the United Nations Conference on the Human Environment held in Stockholm, Sweden in 1972. The conference marked the international community's initial efforts to address global environmental issues and a turning point in national-level awareness. In addition to the declaration of general principles with the Article 109 action plan, the 1972 Stockholm Conference officially addressed a global issue regarding the relationship between the environment and development, between nature and humanity. After 20 years of implementing the Stockholm action plan, in 1992, the United Nations organized the United Nations Conference on Environment and Development (UNCED) in Rio de Janeiro, Brazil (abbreviated as Rio-92). The conference attracted 178 countries (including 114 heads of state), over 1.000 high-level delegates, 9.000 journalists, and 1.400 representatives from

non-governmental organizations. Each package consists of 5 main products of the Conference: Rio Declaration on Environment and Development, Framework Convention on Climate Change, Convention on Biological Diversity, Agenda 21, and Forest Principles. Since Stockholm in 1972 with the message of "Environment and Development", the world community has had to "give in" to pressing environmental issues and development needs to address widespread poverty around the world.

It can be said that the journey towards "sustainable development" leading up to Rio '92 began with the International Union for Conservation of Nature (IUCN) when it addressed the "narrow content" of this term in the "World Conservation Strategy" (1980). The goal at that time was "to achieve sustainable development by protecting biological resources", meaning that only ecological and biological sustainability was emphasized. Afterward, the report "Our Common Future", also known as the Brundtland Report (1987) by the World Commission on Environment and Development (WCED) acknowledged the interconnectedness of development and the environment; sustainable development was defined as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs. According to Professor Marco Adriatic (2020), this definition assumes that we only rely on renewable resources and do not alter the environment as we are doing, in which case the term "sustainability" is being misused. From there, a more practical and feasible definition is needed, which is: sustainable development does not harm the environment and does not deplete resources, and therefore supports long-term development (Marco Adriatic (2020). Although, as we all know, the content of sustainable development defined by WCED was reaffirmed and further developed at the Rio-92 Summit, and supplemented and completed at the World Summit on Sustainable Development held in Johannesburg (South Africa) in 2002 (Rio+10).

The essence of the concept is that sustainable development must be understood as a developmental process, in which the "spatial relationships" between the three pillars (welfare areas) - economy, society, and environment are always optimally adjusted, as well as the "time axis relationship" of needs and benefits between generations are harmoniously addressed. In other words, sustainable development emphasizes the three main aspects of development, and sustainable development principles must be implemented in all three pillars - economic, social, and environmental. In addition, attention should also be paid to other "encompassing" pillars such as culture and sustainable institutions. Specifically, sustainable development involves three main aspects: economic development (especially economic growth), social development (achieving progress, social justice; eradicating poverty and addressing employment), and environmental protection (treating and remedying pollution; restoring and improving environmental quality; fire prevention and forest clearance; sustainable exploitation and use of natural resources, and the ocean). It also involves preserving culture (cultural values, beliefs, and behavior, etc.) and reforming governance (mechanisms, policies, human capacity, coordination capabilities, etc. in implementing sustainable development).

3.2.5. Sustainable development criteria

- Sustainable economic development

Sustainable economic development means fast, safe, and high-quality development. Sustainable economic development requires the development of an economic system where opportunities to access natural resources for economic activities are shared equally. The key focus here is to create shared prosperity for all, not just to concentrate profits for a few, within the limits of the ecosystem and without violating basic human rights. The aspect of sustainable economic development includes some basic contents: (1). Reducing energy and resource consumption through energy-efficient technologies and lifestyle changes; (2). Changing consumption patterns without harming biodiversity and the environment; (3). Equality in access to resources, living standards, healthcare, and education services; (4). Dramatically eradicate poverty and hunger; (5). Clean technology and eco-industrialization (recycling, reuse, waste reduction, and renewable energy regeneration).

A sustainable economy needs to meet the following requirements: (1). Maintaining a high GDP growth rate and per capita GDP. Developed countries with high incomes still need to maintain their growth rate, while poor countries with low incomes need to increase their growth rate even higher. Countries that are currently developing (including Vietnam) need to achieve a GDP growth rate of around 5% per year to be considered to have sustainable economic development in the present conditions; (2). GDP structure is also a criterion for evaluating sustainable economic development. Only when the share of industry and services in GDP is higher than agriculture, the sustainable growth can be achieved; (3). Economic growth must be highly efficient and not accept growth at all costs (Pham Thi Thanh Binh (2018).

- Sustainable social development

Sustainable social development is evaluated by criteria such as the Human Development Index (HDI), income inequality ratio, indicators of education, health, social welfare, and cultural enjoyment are used to evaluate sustainable social development. In addition, social sustainability entails ensuring harmonious social life; maintaining equality among social strata; gender equality; keeping wealth disparity within reasonable limits and tending to converge; and minimizing regional differences in living standards. Social justice and human development, as measured by the HDI index, are the highest criteria for social development, including average income per capita; literacy, education, health, life expectancy; and enjoyment of culture and civilization.

Sustainable social development focuses on equity. Social development always needs to create favorable conditions for human development and strive for everyone to have the opportunity to develop their potential and have acceptable living conditions, without leaving anyone behind. Sustainable social development includes several main contents: stabilizing population, developing rural areas to reduce the pressure of migration to urban areas; minimizing the negative impacts of the environment on urbanization; improving education, eradicating illiteracy; protecting cultural diversity; gender equality, caring for gender needs and interests; enhancing public participation in decision-making processes.

- Sustainable development of the environment

The process of industrialization, modernization, agricultural development, tourism; urbanization, construction of new rural areas, etc. all have an impact on the environment and negatively affect the natural conditions. Sustainability in the environment means that when using natural resources, the quality of the human living environment must be ensured, including air, water, soil, geography, and landscape; regularly evaluated and verified according to national or international standards. Exploiting and using natural resources reasonably, protecting the environment, and improving the quality of the living environment. Sustainable environmental development requires us to maintain a balance between protecting the natural environment and exploiting natural resources for the benefit of humans, to maintain a level of resource extraction within a certain limit that allows the environment to continue to support living conditions for humans and living species on Earth. Specifically, sustainable development in the environment includes the following basic contents: (1). Efficient use of resources, especially non-renewable resources; (2). Developing without exceeding the carrying capacity of ecosystems; (3). Protecting biodiversity and the ozone layer; (4). Controlling and reducing greenhouse gas emissions; (5). Tightly protect sensitive ecosystems; (6). Reducing discharge, mitigating pollution (water, air, soil, food, crops), improving and restoring the environment in polluted areas, ...

Vietnam has implemented several models of the circular economy such as scrap iron recycling, paper recycling, etc. in agricultural models such as garden-pond-livestock, garden-forest-pond-livestock, gas recovery from animal waste, and cleaner production models in small and medium-sized industries. Although there are still some limitations, these models have begun to approach the circular economy.

At present, the whole society has a greater awareness of the issues related to sustainable management and use of resources, environmental protection, and climate change response. Some new models that are closer to a circular economy have been developed, such as ecological industrial park models in some localities; the "No discharge into the environment" concept initiated by the Vietnam Chamber of Commerce and Industry (VCCI); model of processing aquatic by-products; Packaging Recycling Organization Vietnam; Vietnam's global plastic partner... These models, when summarized and evaluated based on fundamental principles and criteria, will contribute to supplementing and improving the circular economy in Vietnam.

(ii). Draw the common relationship, the connection between the results in previous studies. No study examines the relationship between natural capital and circular economy, green economy.

4. Conclusion

Developing a circular economy has become a trend in countries, especially when natural resources around the world are increasingly depleted, helping to solve the problem of balancing economic interests and the environment. The circular economy is an economic model that aims to extend the lifespan of materials and eliminate negative environmental

impacts. Viet Nam is striving to develop a sustainable economy, minimizing negative impacts on the environment, and a circular economy is a model of interest and oriented development.

The shift from a linear economy to a circular economy is a global trend, and Vietnam is not an exception to this trend. That is the best way to address the relationship between economic growth and negative impacts on resource depletion, pollution, and environmental degradation, or in other words, no longer having to trade-off between economic development and environmental protection, achieving multiple sustainable development goals simultaneously. Implementing this direction, requires efforts from all sectors of society, especially businesses as the central driving force, the state plays a role in creating, leading, and engaging the community to change both the perception and behavior of the whole society.

PROMOTING THE GREEN ECONOMY TOGETHER ENVIRONMENTALLY SUSTAINABLE DEVELOPMENT IN VIETNAM: SOME THEORETICAL AND PRACTICAL ISSUES

MA. Trinh Thi Kim Thoa

ttkthoa@ictu.edu.vn

University of Information and Communication Technology, Thai Nguyen University

Abstract

The development of the economy causes great damage to the environment, such as air pollution, water resources; land degradation; biolayer depletion; increasing emissions of greenhouse gases such as CO₂, SO₂, and CH₄... especially global climate change. Therefore, the development of a green economy has become an inevitable trend of countries in order to achieve economic growth, while maintaining environmental and ecological sustainability. In Vietnam, in the past years, there have been many concrete actions to realize the goal of green growth and development of a green economy, initially bringing many practical results. However, the reality is also changing poses many challenges to be solved. The article analyzes the current situation of developing a green economy to protect the environment in a sustainable way in Vietnam, thereby offering solutions to develop a green economy in Vietnam today.

Keywords: *The green economy; Environment; Environmentally sustainable development.*

1. Introduction

The development of the economy causes great harm to the environment, such as air pollution, water resources, land degradation; Deforestation; biolayer depletion; increasing emissions of greenhouse gases such as CO₂, SO₂, CH₄... Therefore, the development of a green economy plays an important role in economic growth while maintaining environmental and ecological sustainability. The XIII Party Congress affirmed the importance of promoting the development of a green economy and a circular economy in association with ensuring environmentally sustainable development. The study focuses on clarifying the theory of the green economy, clarifying the current situation of green economic development for environmentally sustainable development in Vietnam today, thereby proposing some solutions to promote development. green economy development in Vietnam in the coming time.

2. Literature review and Theoretical framework

Green economy issues have been interested by researchers around the world since quite early, such as: Dorling (2007), Luo (2012), Egorova et al. (2015), Maria et al. (2015), Georgeson & Maslin (2019), Sulich (2020), Mikhno et al. (2021). In Vietnam, most of the current research focuses on a number of theoretical issues about green economy, green

economic development in the fields (agriculture, industry, energy,...); experience in developing green economy in the world and lessons for Vietnam; some green economic models (greening the economy, applying biotechnology, responsible business models of all economic sectors,...) such as Kim Ngoc, Nguyen Thi Kim Thu (2015), Do Phu Hai (2018), Nguyen The Chinh (2019), Le Nguyen (2022), Doan Thi Cam Thu (2022)...

Countries around the world have undergone a transition from brown growth to green growth. This transition enhances the quality of life for humanity and mitigates the effects of climate change.

Brown growth is a process of economic development that is mainly based on fossil fuels and does not consider the negative side effects of economic production and consumption on the environment. In contrast, green growth is seen as a shift to a cleaner energy system, more efficient energy consumption and more rational management of natural resources (The World Bank, 2013). The author Hallegatte (2012) believes that green growth will make the growth process save natural resources, create a cleaner and flexible environment, without necessarily slowing it down.

According to Matthews (2013), a brown economy is an economy that depends mainly on fossil fuels, increases the risk of environmental damage and does not consider social problems, environmental pollution and depletion resources. In contrast to the brown economy, the green economy is an economy with the goal of reducing environmental degradation and ecological scarcity, with the goal of sustainable development without damaging the environment. The green economy is often depicted in opposition to the use of fossil fuels and non-renewable resources (Matthews, 2013).

A green economy can also be understood as a dynamic economic transition, with the goal of low carbon, increased resource efficiency and increased people's well-being by using technology and creating create new jobs, while minimizing environmental degradation in the long run (Frone & Simona, 2015).

The data used in this study includes primary and secondary data. Secondary data is collected mainly from published documents such as specialized reports at home and abroad, reports of meteorological agencies and local statistics. Primary data is collected by several organizations such as Communist Party of Vietnam, General Statistics Office, Ministry of Planning and Investment, Ministry of Natural Resources and Environment.

3. Results

3.1. Some theoretical issues on the green economy, environmental sustainability

3.1.1. What is the green economy?

The European Union considers that "a green economy is an economy with smart, sustainable and equitable growth" (European Commission, 2010). The Green Economy Coalition Group defines a green economy as "an economy that produces a better quality of life for all within the ecological limits of the earth" (Green Economy Coalition, 2012).

In 2011, in the Report "Towards a green economy: A path to sustainable development and poverty reduction", UNEP defined a green economy as a green economy that improves living standards and improves equity in society, while significantly reducing environmental risks and ecological resource scarcity. A green economy can be thought of as a low-carbon, resource-efficient, and socially inclusive economy. The core meaning of the green economy is that economic growth goes hand in hand with environmental protection (UNEP, 2011).

The World Bank (WB, 2012) defines a green economy as "economic development that ensures the efficient use of natural resources, which reduces pollution and impacts on the environment, enhances resilience to natural changes, promoting the role of state management of the environment and natural resources in preventing natural disasters".

According to the United Nations Economic and Social Commission for Asia and the Pacific (UNESCAP): A green economy is an approach to achieving economic growth with the aim of economic development while ensuring environmental sustainable development. A green economy focuses on quality innovation of the growth model through promoting ecological efficiency. A green economy is considered a model of higher quality development, in-depth development, and green growth to integrate environmental protection and reduce carbon emissions in production and business as a driving force for development.

From the above definitions, it can be generalized that a green economy is an economy that uses energy economically and efficiently, has low emissions and reduces environmental risks, and improves the quality of life. social balance.

3.1.2. Environmental sustainable development

The United Nations World Commission on Environment and Development defines "sustainable development" as "development that meets the needs of the present without compromising the ability of other countries to meet their own needs " future generations" (World Commission on Environment and Development, 1987). The Earth Summit on Environment and Development held in Rio de Janeiro (Brazil) in 1992 stated that "sustainable development" is a process development has a close, reasonable and harmonious combination of three aspects of development, including economic development, social development, and environmental protection.

Thus, sustainable development is a development that ensures economic growth based on of rational use of natural resources and protection of the natural environment to satisfy the needs of the next generation. Today, while not affecting the conditions and ability to satisfy the needs and living environment of future generations.

Environmental sustainable development is the rational use of natural resources, maintaining a stable resource base, and avoiding the over-exploitation of renewable resource systems. Environmental sustainable development needs to maintain biodiversity, atmospheric stability, and other ecological activities, needs to limit environmental pollution including urban and industrial pollution, needs to must manage and treat well solid waste and hazardous waste, be able to prevent and minimize the impacts of climate change and natural disasters.

The green economy towards environmental sustainable development is a high-quality development model that focuses on innovating the quality of the growth model in depth, integrating the objectives of environmental protection, economic use, and environmental protection. Energy and natural resource efficiency, have low emissions and reduce environmental risks and improve social equity. Environmental protection, sustainable management and use of natural resources, and response to climate change are considered key issues of the green economy.

3.1.3. The role of the green economy in environmentally sustainable development

First, the green economy mitigates the impact of climate change. According to calculations, only about 1.25% of global GDP needs to be invested in improving energy efficiency across sectors and developing renewable energy, including second-generation biofuels, to worldwide energy consumption could be reduced by 36% by 2030 and annual CO₂ emissions would decrease from 30.6 billion tons in 2010 to 20 billion tons in 2050. Plus, thanks to agriculture Green, the green economy scenario is estimated to reduce greenhouse gas concentrations to 450ppm by 2050, a level that is considered reasonable and sufficient to limit global warming to 2 degrees Celsius. According to UNESCO, green investments in the forestry and agricultural sectors will help reverse the current trend of forest land decline, renewable about 4,5 billion hectares of this important resource over the next 40 years. Investing in green agriculture improves productivity, produces more food, reduces land use for agriculture and livestock by 6%, and improves agricultural land quality by 25% by 2050.

Second, the green economy encourages the use of renewable energy, and new energy more efficiently to protect the environment. The green economic model recognizes the value and role of investment in natural capital, creating jobs, as a pillar to reduce poverty. Therefore, instead of using fossil fuels, the green economy uses renewable energy and low-carbon technology, encouraging more efficient use of resources and energy. As natural resources are increasingly depleted and biodiversity declines and environmental pollution increases, the use of renewable energy will help reduce greenhouse gas emissions and risks of chemical fuel price fluctuations jelly.

Renewable energies are energy sources with almost inexhaustible reserves, long-term potential, and environmental friendliness such as wind, solar radiation, tides, biogas, wood, biomass, etc. block (straw, rice husk, leaves)... The United Nations Environment Program emphasizes the use of renewable energy (solar energy, wind energy, geothermal energy, biogas...); Designing and building greenhouses with the use of clean energy, efficient use of water, consumption of green products, environmentally friendly materials; Environmentally friendly transport with the increasing use of biofuels, cycling on the streets and public transportation by steam and electric vehicles...in the green economy.

Thus, the use of renewable energy is also one of the new driving forces of the green economy, which is environmental protection, towards sustainable environmental development.

Third, a green economy that reduces carbon emissions opens up sustainable urban life and protects the environment. Urban areas today are home to more than 50% of the

world's population, consume 50% - 60% of energy, and emit 75% of total greenhouse gas emissions. Rapid urbanization is putting increasing pressure on clean water supply, drainage, and public health, often resulting in poor infrastructure, declining environmental performance, and public health care costs. plus high. As urbanization and increasing urban affluence will continue to drive the growth of energy demand in cities, technology and behavioral changes in urban energy systems will be strategies to achieve long-term sustainability of global energy use - including the necessary carbon emissions cuts.

3.2. Current status of green economic development for environmentally sustainable development in Vietnam today

3.2.1. These achievements

In recent years, climate change in Vietnam has continuously set new records in terms of temperature, rainfall, sea level, occurrence frequency and influence of super typhoons, floods and storms. tropical depression... Vietnam is one of the countries most heavily affected by climate change and sea level rise. This is considered a direct cause of changes in the environment and the earth's ecology and is a risk of negative impacts on the socio-economic development of all countries in the world. The World Bank estimates that climate change will reduce Vietnam's GDP by 3.5% by 2050.

Along with the goal by 2030, Vietnam will basically become a modern industrialized country, in which a number of industries with international competitiveness and deep participation in the global value chain have increased. pressure on the environment and natural resources. Therefore, green economic development is an inevitable trend, both ensuring the goal of economic modernization, environmentally sustainable development and enhancing the ability to respond to climate change. Research to properly assess the impact of climate change, reduce environmental degradation and improve resilience and adaptation to climate change is an important and urgent goal that needs to be resolved soon to ensure green development in the future.

In the context of the Covid-19 epidemic, many countries are promoting the recovery of economic growth in the direction of green growth or "green recovery". For Vietnam, the shift to a green economy and green growth is not only an inevitable choice but also an opportunity to become a pioneer in the region, catching up with the development trend of the world.

- Firstly, the policy on green economic development, environmental protection

Vietnam is one of the few countries that is heavily affected by climate change and has suffered many negative impacts from natural disasters and epidemics. According to calculations, in the past 20 years, in our country, all kinds of natural disasters have killed more than 13,000 people and caused economic losses of more than 6.4 billion USD (Tuan Ngoc, 2022). According to climate change scenarios. According to the Ministry of Natural Resources and Environment, by the end of the 21st century, a 1m rise in sea level could directly affect the lives and livelihoods of about 20% of the population and the loss could reach 10% of GDP per year (Ministry of Natural Resources and Environment, 2016).

Recognizing the impacts of climate change on people's lives, over the years, Vietnam has had many green economic development policies. The orientation and goal of greening the economy are detailed in the Prime Minister's Decision No. 1393/QĐ-TTĐ dated September 25, 2012, approving the National Strategy on Green Growth 2011-2020. and a vision to 2050; Decision No. 2612/QĐ-TTĐ dated December 30, 2013, of the Prime Minister approving the Strategy on using clean technology for the period to 2020, vision to 2030; Decision No. 1658/QĐ-TTĐ dated October 1, 2021, of the Prime Minister approving the national strategy on green growth for the period 2021 - 2030, with a vision to 2050. The Prime Minister also approved the National Action Program on sustainable production and consumption from 2021-2030 to exploit and use resources in sustainable, and environmentally friendly as well as create stable jobs. decisions and green jobs, thereby promoting sustainable lifestyles and improving the quality of life. The 13th Party Congress affirmed the policy of building a green economy, a circular economy, and being environmentally friendly: "Continue to develop the country quickly and sustainably, ensure macroeconomic stability, strongly renew the growth model, improve productivity, quality, efficiency and competitiveness of the economy. Actively and effectively adapting to climate change, managing, exploiting, rationally, economically, efficiently and sustainably using natural resources; taking the protection of the living environment and people's health as the top goals; resolutely eliminate projects that cause environmental pollution, ensure the quality of the living environment, and protect biodiversity and ecosystems; build a green economy, circular economy, environmentally friendly". (Communist Party of Vietnam, 2021).

Secondly, transforming the economic production model, renewing the growth model from "brown" to "green" and integrating environmental protection goals.

Transforming the economic structure, renewing the growth model from "brown" to "green", from intensive exploitation of natural resources to development based on ecosystems, digital economy, circular economy, and carbon low is the development trend of the world. The production technology in Vietnam today compared to the world is mostly old technology, large energy consumption, and poor waste treatment leading to low production efficiency, generating a large amount of polluting waste, and increasing costs. increase greenhouse gas emissions. Green production is becoming one of the models targeted by many businesses, to meet new requirements and be in line with the general development trend of the world. At the same time, this model also helps to improve the position and competitiveness of enterprises in both domestic and foreign markets.

In the field of agriculture in Vietnam, green farms have been established with scientific production plans and strict production processes; production development is associated with the creation of a sustainable ecological environment and biodiversity. In addition, many local farmers have joined agricultural cooperatives to produce organically, without using chemical fertilizers and pesticides, providing clean products for consumers. use. For example, at Huy Long An Company Limited, fruit trees such as bananas, grapefruits, and durians, raising Australian cows, Japanese cows, and shrimp... are all

applied by enterprises under the continuous clean production model, self-contained according to the lowest standard is VietGAP.

In the industrial sector, enterprises have limited old and outdated technology; promote research and application of science and high technology to production. According to the data of the General Statistics Office, in the period 2011 - 2015, the proportion of high-tech products in the total industrial production value averaged 18.37% (UNDP, 2015). In the period 2016 - 2020, this number also increases from 63.9% in 2016 to nearly 80% in 2020 (Nguyen Tuan Phong, 2021). Besides, the industrial production sector has had positive changes. The rate of industrial enterprises applying cleaner production technology increased from 11% to 32% in the period 2011-2015, the industries that consume a lot of energy tend to decrease, especially the steel industry (down 8.09%), cement (down 6.33%), textile yarn (down 7.32%) (Lan Anh, Thu Phuong, 2019).

In the service sector, people and investors have gradually shifted their shopping habits to "green" consumption channels and prioritized health protection and renewable energy. To meet the needs of people to buy clean and clear products, clean food companies were born such as Sea Wolf, Uncle Tom, Home Food, and Hano Farm... Restaurants, food shops, supermarkets, etc. switch to using "green" products such as packaging and items made of environmentally friendly materials instead of nylon, single-use plastic such as milk tea shops using bamboo or stainless steel straws instead of plastic straws; Supermarkets use banana leaves to pack vegetables, food instead of plastic bags, use environmentally friendly packaging, etc. The survey results of Nielsen Vietnam Company show that Vietnamese consumers are increasingly more interested in "green" and "clean" issues, they are willing to pay more for brands with "green" and "clean" commitments. Specifically, up to 80% of consumers are concerned about the long-term harm of artificial ingredients and 79% are willing to pay extra to buy products that do not contain unwanted ingredients (Ministry of Industry and Trade, 2017).

Third, use energy economically and efficiently, renewable energy to reduce emissions and protect the environment. Vietnam is one of the countries most severely affected by climate change. Extreme weather events occur more and more frequently and erratically (long-lasting heat, drought, storms and floods, saltwater intrusion, and sea level rise in coastal areas...), and the causes are related to global warming and greenhouse gas emissions. It is estimated that the total amount of greenhouse gas emissions in 4 sectors: energy, agriculture, and waste in 2020 are 466 million tons of CO₂ and in 2030 will increase to 760.5 million tons of CO₂ (Ministry of Planning and Investment, 2021). In addition, Vietnam is currently facing the negative impacts of climate change. Large amounts of greenhouse gases have serious consequences for the atmosphere, especially in big cities, affecting the atmosphere. If these effects are not reversed by emission reduction measures,

Currently, Vietnam has promoted the development of renewable energy, and clean energy to reduce emissions. Biomass energy projects, such as the Bio-power plant in Phu Tho, the biomass thermal power plant in Binh Phuoc, rice husk-fired thermal power plant in Can Tho. The electricity of Vietnam has built 113 solar and wind power projects, with a total

capacity of wind and solar power sources of nearly 23,000MW, of which, solar power is about 11,200 MW, and wind power is about 11,800 MW. Bringing Vietnam into the top 10 countries with the highest installed solar capacity globally by 2020. With great potential for solar power and ambitious green energy targets by 2050, Vietnam South has many opportunities to become a global leader in renewable energy.

In the fields of agriculture, forestry, and construction, there have also been significant advances in the process of implementing green growth. Many programs have been put into practice, bringing efficiency in production and business, such as Good Agricultural Practices (VietGAP) for key agricultural products (such as vegetables, tea, rice, etc, and coffee), water-saving irrigation procedures for rice, for dry crops; biogas program in the livestock industry, saving and improving energy efficiency in fishing; action plan to reduce greenhouse gas emissions in cement production; implementing integrated solid waste management; green urban development or action plan to reduce CO2 emissions in civil aviation activities.

3.2.2. Limitations, existing in the process of developing a green economy toward environmentally sustainable development

Vietnam's green economy is also facing many difficulties and challenges.

- The lifestyle and consumption patterns of a part of some people are still wasteful, destroying resources, unfriendly, and in harmony with nature. Awareness and understanding of green growth, and building a green economy towards sustainable development, require extensive research and knowledge dissemination in both political systems, businesses, and industries. community.

- Labor quality is not high, science and technology level is still limited. Besides, the economic growth model is still mainly broad-based, dependent on foreign direct investment. Labor restructuring in the market is still slow, unable to keep up with economic restructuring: In 2022, 53.61 million people aged 15 and over are employed, including 17.0 million workers in industry and construction (accounting for 33.6%); service sector is 19.7 million people (accounting for 38.9%); labor in agriculture, forestry and fishery reached 13.9 million people, (accounting for 27.5%). While, in the economic structure in 2022, the agriculture, forestry and fishery sector accounts for 11.88%; industry and construction accounted for 38.26%; service sector accounted for 41.33%; product tax minus product subsidies accounted for 8.53%.

- The legal system is in a transition period that is not synchronized, not suitable for the trend of globalization and towards green growth;

- The efficiency of using resources is low and wasteful, natural resources (natural capital), especially biological resources, are severely degraded, non-renewable resources are exhausted; Production technology is outdated, consuming a lot of energy; The "brown" economic sectors are accounting for a large proportion of the economy. The old technology produced in Vietnam today compared to the world is mostly old technology, large energy consumption, and poor waste treatment leading to low production efficiency, generating a

large amount of polluting waste and increasing costs. increase greenhouse gas emissions. Clean energy production industries such as nuclear energy, wind energy, solar energy, biomass, and geothermal... have not yet developed. In addition, many supporting industries, solving environmental problems, environmental services, and recycling industry... are still weak;

4. Discussion and Conclusion

Developing a green economy is a trend of the world and also a goal towards environmentally sustainable development. The green economy meets both economic growth and environmental protection goals. The green economy has an important role in environmental sustainability: mitigating the impact of climate change; reducing energy consumption, increasing the efficiency of clean energy use; reducing carbon emissions to ensure the health of urban residents. In the strategy of developing a green economy, Vietnam has achieved positive results, but there are still certain difficulties. Proposing solutions to develop a green economy associated with environmental protection is very necessary for Vietnam today.

Firstly, propaganda to raise awareness of the political system, businesses, and the community about developing a green economy in association with sustainable environmental protection goals. Therefore, it is necessary to develop and implement communication and propaganda projects to raise awareness of the whole political system, businesses, and the community about implementing green growth and contributing to building a developed country. lasting; Extensive propaganda for people to participate more deeply in the green economy and green growth chains, thereby raising people's awareness of environmental protection and natural resource protection in production activities. production and consumption in particular and in economic development

Secondly, Completing the legal corridor suitable for green economic development. These can be financial measures, national policy reforms, international cooperation through trade, aid, and market development. .. To develop laws and regulations to promote, encourage and support the development of organizations, individuals, and businesses with the direction of green development, green business, and environmental protection. In addition, there should be sanctions for organizations and individuals that destroy the environment in the process of production and business. Resolutely not allowing foreign corporations and organizations that tend to cause harm to the environment to be allowed to invest in a business, construction, and production. Asianapply green economic tools, and uniformly use the national system of standards and green classification criteria for production and consumption activities.

Thridly, increase investment in science and technology development; especially promoting research and research cooperation with international partners in the fields of industries serving green economic development, such as: using renewable energy, production technology that saves resources, consumes less energy, seeking low-emission technological solutions, supporting conditions for technology transfer, and promoting the deployment of these technologies in all industries and fields to achieve the goal of economic growth while ensuring national emission reduction target.

FACTORS INFLUENCING BEHAVIOUR OF HOUSEHOLD SOLID WASTE SEPARATION IN THANH XUAN DISTRICT, HANOI CAPITAL

Dr. Ngo Thanh Mai
thanhmai@neu.edu.vn

Do Duc Duy
duyd.nevents@gmail.com

Faculty of Environmental, Climate Change and Urban Studies
National Economics University, Hanoi, Vietnam

Abstract

Although some programs of waste separation at source have been deployed over the last decades in Hanoi capital, they have stopped at the level of pilot-programs and have generally not been replicable. Using the theory of planned behavior (TPB), this study examines factors associated with waste separation behaviors by analyzing responses to questionnaires distributed in Thanh Xuan district, Hanoi capital. Results from the survey of 75 valid respondents in Thanh Xuan district have revealed that two factors, namely: household attitude and subjective norms, have impacts on households of solid waste separation behavior. These findings suggest that it is indispensable to build up educational campaigns that may raise people's awareness and beliefs about the benefits of solid waste sorting in conserving natural resources as well as reducing the use of landfills and emissions of greenhouse gasses. Moreover, public media and communication campaigns should be designed appropriately with the aim to attract more and more people to perform waste sorting behavior.

Keywords: *Municipal Solid Waste, Solid Waste, Source Separation*

1. Introduction

During past years, Viet Nam has to face numerous difficulties and challenges in solid waste (SW) management due to urbanization process, rapid economic and population growth. According to the Ministry of Natural Resources and Environment (MONRE, 2020), the amount of SW increase at a rate of 12%/year, equivalent to 64,658 tons/day. It is estimated that in urban areas, the average amount of municipal solid waste (MSW) will growth by 10-16%/year (more than 13 million tons/year, accounting for 55% of the total volume of SW generated in the country). Although volume of SW is large, the qualifications of infrastructure system and management capacity are still limited, which has not met the needs of the development process, causing a lot of pressure on the environment and society.

Separation of SW at source is an important segment of SW management. It has been considered as the first step in this management chain, plays a critical role in determining the quality and quantity of waste flowing into the follow-up processing procedures, such as recycling, transportation, landfilling, incinerating, and composting. It is also a fundamental condition in *closing the loop of materials*, which is expected to reverse the negative impacts

of solid waste on the environment and the scarcity of natural resources (Zhu, 2013). In Vietnam, although pilot programs of waste separation at source have been deployed since the 1996, they have not been scaled up. Most of the SW generated is disposed of in landfill sites, causing severe pollution and overload of waste.

Thanh Xuan district is located in the southwest of the Hanoi capital, with an area of 9.11 km². With an average economic growth rate of 6.1% and an increase in population of about 8000 people (Hanoi Statistical Office, 2022), the district has many environmental problems, especially MSW. SW daily generation in the district is about 247 tons/day, equivalent to an average of 0.8 - 0.9 kg/person/day, of which food waste accounts for about 51.9%, and about 48.1% of household waste is recyclable (URENCO, 2021). To promote the recycling and reuse and reduce the amount of SW emitted in the environment, the active participations from the community in MSW classification activities play an important role. In this paper, investigation and evaluation of MSW source-separated collection are carried out. Based on these analyzes, some suggestions and recommendations are proposed to encourage households' participation and improve MSW management.

2. Research Method

2.1. Data collection

- *Primary data collection:* To identify the factors affecting the behavior of households' waste classification in Thanh Xuan district, questionnaires has been designed to collect opinions of households by randomly visiting households at 4 wards, including: Khuong Dinh, Khuong Trung, Ha Dinh, Thuong Dinh from 3/2023 to 4/2023. A total of 84 questionnaires were delivered, and 81 attained samples. After screening and removing invalid questionnaires (those were not fully completed or the answers were one - scale dimension), a total of 75 valid samples were used for further analysis. In this study, the questionnaire includes two main sections, which were designed to fulfill the research objectives and several key requirements from the research hypotheses. The first section focuses on the measurement of the construct in the research model. Questions on attitude towards waste separation, social norms, perceived behavioral control, knowledge about waste separation, laws and regulations, propaganda, and behavioral intentions were included. Studying factors impacting separation behavior intention uses the scale Likert that is 5 levels. In the second section, questions on demographic characteristics were asked, including gender, age, and education level.

- *Secondary data collection:* The study is based on information collected from documents including documents, laws, projects, and research reports related to the behavior of MSW classification in the period from 2018 to 2022. The author also collects information and statistics from the General Statistics Office, the Ministry of Natural Resources and Environment on MSW management.

2.2. Methodology

- *Quantitative analysis*

To investigate factors influencing on household's separation, the data is calculated and processed by excel and SPSS.29 software.

Frequency statistics: the authors use excel to re-statistic the frequency and percentage of factor groups, usually applied to qualitative variables. In this study, they are variables about demographic characteristics such as gender, age, income, education level. The results of frequency statistics help to evaluate the structure of each variable.

Methods of data processing: SPSS software are employed for exploratory factor analysis (EFA), scale testing (Cronbach's Alpha). Next, after the steps of checking the factors, the author removed the bad variables and continued to use SPSS software for correlation analysis and regression analysis - testing the hypotheses.

- *Theory of solid waste separation behavior*

Under the concept of pro-environmental behaviors, the Theory of Planned Behavior (TPB) has been applied to predict the likelihood or intention that individuals will engage in various pro-environmental behaviors (Ajzen, I., 1991). For SW management, many studies rely on TPB theory to prove that psychological factors including attitude, subjective norms, and perceived behavioral control (PBC) are main predictors to waste separation intentions and are based on their positive intention. Gold (2011) suggested that an individual's behavior can be predict better with a model that includes moral obligation, these additional variables are all consistent with the original TPB. In addition, Zhou, M. (2019) states that waste segregation advertisements are found everywhere in newspapers, television, radio and on the internet or local authorities take measures. If the policy promotes the classification of people and makes it widely available, it will contribute to increasing the behavior of garbage segregation.

Therefore, to assess the factors affecting the behavior of SW classification in Thanh Xuan district, this study is based on the TPB and adds two more variables, namely personal moral obligation. support policies of local governments.

(1) *People's attitude (AT)*

People's attitude is the positive or negative attitude of an individual in performing a particular behavior. Attitude is a relatively stable psychological structure that many studies have confirmed and predicted the influence of this factor on the behavior of participating in environmental protection. Studies have shown that individuals with a positive attitude are more likely to be willing to participate (Zhang Y. et al., 2019). This study expects that if people have a positive attitude towards environmental protection, the level of participation in the classification of solid waste will be high and vice versa.

(2) *Subjective norms (SN)*

Subjective norms refer to the influence of external social pressures on an individual's particular behavior. They are usually the regulations of units, mass organizations, authorities or from family, friends and colleagues. McEachan R.R.C. (2011) have shown that the greater the external social pressure, the stronger the individual's willingness to participate in environmental protection activities. In this study, subjective norm refers to the influence of external social pressure on people's willingness to separation SW. The greater the social pressure, the higher their willingness to participate and vice versa.

(3) *Perceived behavioral control (PC)*

Perceived behavioral control measures an individual's subjective perception of performing a particular behavior (Ajzen I., 1991) and whether that action is controlled or restricted. The proposed relationship between perceived control behavior and intended/actual behavior is based on two hypotheses: first, an increase in perceived behavioral control will lead to an increase in behavioral control. intends to perform the act and is likely to result in the performance of the action; second, perceived behavioral control will to some extent directly affect behavior where perceived control reflects actual control (Armitage, C. J., & Conner, M., 2001). Based on this argument, if people have confidence in their own garbage sorting ability, the higher the willingness to participate and vice versa.

(4) *Obligations of moral awareness (MO)*

Moral obligation refers to an individual's subjective judgment. This factor reflects the individual's self-expectations and attitudes towards specific behaviors, which are shaped by personal norms and values. Zhang (2019) argues that individuals feel proud if their actions are in line with the norm; otherwise, they will feel guilty. Moral obligation has also been included by Gold (2011) in predictive behavioral analysis. The results show that Moral obligation has a positive impact on environmental protection behavior. The individual ethical obligations in this study were measured by a sense of responsibility, duty and guilt if they did not sort their waste with the expectation that it would have a positive effect, promoting sorting behavior.

(5) *Policy of government (PG)*

Yu, He, Li, Huang, and Zhu (2014) proved that the laws and regulations had a positive effect on the willingness of residents to separate. Wang et al. (2016) found that promulgation and public spread of the laws and regulations improved environmental awareness among residents and in turn making them ready to sort waste. Noehammer and Byer (1997) founded that compulsory recycling programs launched by the government had a higher participation rate than voluntary resident recycling. Vietnam is a government-leading country which means all levels of government are responsible for issuing legislation on waste separation. In a nutshell, laws, and regulations ruled by the government play a vital part in waste sorting.

In addition, propaganda could motivate residents to realize the significance of household waste separation and hence perform separate collections better. De Feo and De Gisi (2010) presented the idea that propaganda and citizen encouragement could encourage residents to separate waste.

3. Results

3.1. Descriptive statistics of the survey sample

Among 75 survey participants, the number of men participating in the survey is 48 people, accounting for 64%, and women are 27 people (accounting for 36%). Age is a factor that impacts on the knowledge of respondents. Different ages may have different perceptions and understandings about SW classification due to their different knowledge. In the survey,

the most common age is from 22 to 60 years old, with 41 people, accounting for 41%. Regarding the respondents' education level, the highest percentage of education is college or university graduates, accounting for 40% of the respondents. Among the total 75 candidates, highest percentage of income ranges from 15 to 30 million VND/person/month, accounting for 40% and there are 19 people with income over 30 million VND/person/month, accounting for 25.4%.

3.2. Testing for reliability of the scales

Cronbach's Alpha analysis was used before the EFA factor analysis to remove unsuitable variables because these factors can create dummy factors. Cronbach's Alpha reliability coefficient only indicates whether the measures are related or not; does not indicate which observed variables should be removed and which should be kept. Cronbach's Alpha is used to evaluate the reliability of the scale based on the criteria of Cronbach's Alpha coefficient > 0.6 and the total variable correlation coefficient > 0.3 .

Table 1. Reliability of indicators

Item Code	Indicator	Item-total correlations	Cronbach's Alpha after deleting variables	Cronbach's Alpha
AT1	Sorting garbage helps to protect the environment and conserve resources, we should do	.694	.677	.801
AT2	I can create a model for children by doing household waste separation	.609	.767	
AT3	Waste separation demonstrates the effectiveness of personal hygiene	.640	.735	
SN1	Does your family support you in sorting household waste?	.778	.812	.877
SN2	Do your friends support you in sorting household waste?	.748	.839	
SN3	Does your neighbor assist you in sorting your trash?	.763	.826	
PC1	Do you have enough time to do waste separation?	.774	.873	.900
PC2	Does your home have enough space to store sorted trash?	.794	.865	
PC3	Does your local government or community provide you with complete facilities for waste separation (e.g. separation bags, sorting bins)	.780	.870	
PC4	Is it convenient for your home to do garbage separation?	.763	.877	
MO1	Garbage separation is an ethical act to protect the ecological environment, everyone has a duty to do so	.738	.784	.854
MO2	Separating waste is an act of thrift, everyone has an obligation to do so	.683	.835	
MO3	Do you feel embarrassed when waste is thrown in the trash without classification?	.757	.767	

Item Code	Indicator	Item-total correlations	Cronbach's Alpha after deleting variables	Cronbach's Alpha
PG1	The local government pay great attention to the issue of waste segregation and has actively campaigned for people to participate in the waste separation.	.690		.789
PG2	Local governments and communities provide a scientific, efficient and concise waste classification guideline	.690		
AC1		.744		.852
AC2		.744		

Source: Calculation results from survey data, 2023

From the results of reliability testing through Cronbach's Alpha coefficient in table 1, it can be seen that all factors have alpha coefficients greater than 0.6 and all variables have correlation coefficients with the total variable greater than 0.3 is satisfactory.

- *EFA exploratory factor analysis*

EFA factor analysis was conducted to evaluate the convergent and discriminant values of all observed variables, converging observed variables on a few large factor groups and distinguishing these groups of factors. The EFA method requires the observed variables to meet 5 criteria on the KMO coefficient in the range of 0.5 - 1; Bartlett's test has Sig coefficients. ≤ 0.05 ; Eigenvalue ≥ 1 ; Total variance extracted $\geq 50\%$ and Factor loading factor ≥ 0.6 .

- Exploratory factor analysis for all independent variables

After testing the reliability of Cronbach's Alpha, the scales were next evaluated by exploratory factor analysis (EFA). The factor analysis will be conducted with all observed variables, then will remove the variables with low transmission coefficient.

For the first time, 15 observed variables were included in the analysis. KMO coefficient = .890 (>0.5). However, the observed variables, CS1 and CS2 were excluded due to their low transmission coefficient.

For the second time, the PG1 and PG2 variables were removed, and the remaining 13 variables were included for factor analysis. The transmission coefficients are all greater than

Table 2: KMO test results of independent variables

KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.900
Approx. Chi-Square		637.670
Bartlett's Test of Sphericity	df	78
	Sig.	.000

Source: Calculation results from survey data, 2023

The results of KMO analysis show that: KMO coefficient = .900 > 0.05, so factor analysis (EFA) is suitable with the research data set. Bartlett test is 637,670 with significance level Sig < .001, proving that the data used for factor analysis is completely appropriate. Total Variance Explained = 66.786% > 50%, so it meets the requirements, indicating that the above 5 factors explain 66.786% of the data variation. All observed variables have factor loading > 0.6.

- Exploratory factor analysis for the dependent variable

Table 3: KMO test results of the dependent variable

KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.500
	Approx. Chi-Square	58.534
Bartlett's Test of Sphericity	df	1
	Sig.	.000

Source: Calculation results from survey data, 2023

The results of the EFA analysis of the dependent variable show that: The observed variable of "household waste sorting behavior" is grouped into 1 factor, no observed variable is excluded. EFA is consistent with the coefficient KMO = .500, the total variance extracted is 87.215% > 50%, so the EFA model is suitable; observed variables have factor loading coefficients > 0.5, significance level Sig. of Bartlett's test is <.001. So, the research model removes the variable of the local government policy

3.3. Multiple regression analysis

The regression model has the following form: $SI = \beta_0 + \beta_i X_i + e$

Where: SI: dependent variable; X_i : Independent variables

β_0 : Regression constant; β_i : Regression weight; e: Error

Regression analysis includes 4 independent variables: people's attitude (AT), subjective norm (SN), perceived behavioral control (PC), moral cognitive obligation (MO) and 1 auxiliary variable that belongs to the act of classifying domestic waste (AC)

Table 4. Results of Regression Analysis

Coefficients^a

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
	B	Std. Error	Beta			Tolerance	VIF
(Constant)	-.330	.331		-.997	.322		
ATtb	.585	.104	.499	5.647	.000	.521	1.920
SNtb	.499	.111	.414	4.476	.000	.476	2.100
PCtb	.021	.113	.020	.183	.856	.349	2.868
MOtb	-.002	.102	-.002	-.022	.982	.397	2.518

Source: Calculation results from survey data, 2023

The above results show that, with the significance level $\alpha = 5\%$, the perceived behavioral control variable and moral obligation are not significant and cannot explain the dependent variable.

From the regression results, the behavior of household waste classification is represented by the following formula:

$$SI = 0.414*SN + 0.499*AT$$

$\beta_1=0.414 > 0$ indicates that the higher the subjective standards of household waste classification, the higher the behavior of household waste classification.

$\beta_2= 0.499 > 0$ indicates that the higher the attitude of the person about the classification of household waste, the more the behavior of the household waste classification increases.

Thus, out of the given factors, only 2 factors have an impact on the behavior of people's household waste classification in Thanh Xuan district, Hanoi. The obtained results are quite consistent with the characteristics of the respondents.

Each of these factors represents a different group of observed variables and the importance of the observed variables for the representative factor is evaluated through the factor loading coefficient. Accordingly, the higher the factor loading coefficient, the more important the role of that observed variable for the representative factor is.

The normalized regression coefficient shows that the greatest influence on the household waste classification behavior of people in Thanh Xuan district, Hanoi based on the absolute value of the Beta coefficient. The greater the absolute value of the factor Beta, the greater the influence of that factor on the dependent variable.

Based on the model's regression coefficient table, it can be seen that the factor that has the greatest influence on the behavior of people in household waste classification in Thanh Xuan district, Hanoi is the people's attitude with the number β_2 is 0.499.

Cronbach's Alpha results for the independent variable scales of the subjective norm factor are relatively high (0.877), showing that this factor plays an important role in the behavior of household waste classification of households in Hanoi. Thanh Xuan district.

In the group of factors about subjective standards when classifying solid waste, the observed variable SN3 "does your neighbors assist you in classifying domestic waste" is the most important value with the highest transmission coefficient. (=0.801).

Next is the variable SN2 "does your friends support you to classify garbage with a transmission coefficient of 0.797 and finally the variable SN1 "does your family support you in sorting domestic waste" systematically? The lowest transmission number is 0.765.

Subjective standards have a positive impact on the behavior of domestic waste classification, when people have the right awareness or have the support of friends, relatives and the community, the garbage classification will be done well. than. This result is also found in the studies Ru et al. (2019), the author and collaborators said that people have a

high sense of responsibility and obligation towards the environment and community, the waste classification of they will be stronger.

The second factor affecting on the behavior of household waste classification is the attitude of the people. The results of Cronbach's Alpha reliability analysis are quite good at 0.801, showing the important role of this factor in the household waste classification behavior of households in Thanh Xuan district, Hanoi Capital.

4. Conclusion

With survey results of 75 households in Thanh Xuan district, Hanoi city, this study applied an extended theory of planned behavior to analyze factors affecting waste source-separation behavior in urban areas. From the initial 5 factors, after the process of testing and analyzing, the results revealed that there are two factors affecting the behavior of household waste classification, including household attitudes, subjective standards. From this analysis, combined with the views of the central and local government, some solutions have been proposed. As the study shows, attitude towards waste separation is the primary influencing factor in activating residents' household waste separation intention. That shows the fact that those who participate actively in waste separation do so mainly because they understand that waste separation is a cost-effective way of enhancing environmental quality and increasing socio-economic sustainability. In addition, knowledge about waste separation is the strong influence on household waste separating behavior. Consequently, it is indispensable to build up educational campaigns that may raise people's awareness and beliefs about the benefits of waste sorting in conserving natural resources as well as reducing the use of landfills and emissions of greenhouse gasses. By realizing how beneficial waste separating is, it would motivate residents to sort household waste and further foster these habits among residents. Besides that, the findings from this study revealed the significance of social pressure in developing residents' household waste separation intention. Therefore, public media and communication campaigns should be designed appropriately with the aim to attract more and more people to perform waste sorting behavior.

Abstract

The objective of this study is to test the relationship between factors and profitability of real estate companies listed on the stock exchange in Vietnam in the period 2017-2022. The topic uses a multivariable linear regression model and a data table for the data of 74 Vietnamese real estate enterprises under the support of Stata software. And to test the influence of factors affecting the profitability of Vietnamese real estate enterprises, the models : OLS least squares regression method, REM random effect model and fixed effect model. FEM definition is also used. The research results show that the factors of enterprise size, debt-to-equity ratio and GDP have a positive influence while factors such as operating time, quick ratio and turnover ratio are not positive. Total asset cycle is not statistically significant and needs further study.

Keywords: *Real estate, corporate profits, stock exchange listing, OLS, REM, FEM.*

1. Introduction

Since Vietnam has joined the World Trade Organization (WTO), the economic situation has had many positive changes that have opened up many investment opportunities and increased income, so the needs of the people, especially especially the increasing demand for housing. Therefore, the development of real estate businesses is inevitable. The real estate market (real estate) is currently one of the economic sectors that play an important role, having a close relationship with the stock market, capital market, financial and

monetary market... Before 2008, Real estate is one of the fastest growing industries. However, in recent times, after the sudden growth of the real estate market, people have witnessed a period of decline in this market. In addition, in recent times, along with the crisis caused by the Covid-19 pandemic, the management and development of the real estate market still has many limitations. The government has introduced policies to curb inflation and control real estate credit, which "cools down" the market. That has brought many difficulties and challenges for businesses. In such competitive conditions, how to maintain profitability is a problem that real estate businesses are still constantly looking for answers to. This study will learn more deeply about the relationships of factors affecting profitability when the factors are changing markedly compared to the previous time and make judgments to help real estate businesses. Improve efficiency in the current context and at the same time help investors invest in securities in the real estate sector more effectively.

2. Method

2.1. Data collection methods

The data used in the model is secondary data collected from the financial statements of 74 real estate enterprises that have participated in listing on the Vietnam stock market. The total number of observations for the document is 359 for the 6-year period from 2017 to 2022. Analytical data on the overview of the economy and the real estate industry are obtained by the author from the General Statistics Office of Vietnam (GSO), the General Department of Family Planning, the State Bank of Vietnam (SBV), the Ministry of Finance (GSO), the State Bank of Vietnam (SBV), the Ministry of Finance. MOF), World Bank (WB), International Monetary Fund (IMF), Asian Development Bank (ADB), World Economic Forum (WEF), Provincial Competitiveness Forecast Center (PCI).

2.2. Data Analysis Methods

The topic uses a multivariable linear regression model and data tables for 74 real estate companies listed on the stock market in Vietnam in the period 2017-2022 with the support of Stata software. To test the factors affecting the profitability of real estate companies listed on the stock market, the study will use one of the OLS models, REM models, and FEM models.

Based on previous research results and to match the current situation of the real estate business in Vietnam, the author proposes a panel data regression model of the form:

$$E(Y/X_t) = \beta_0 + \beta_1 X_{1t} + \beta_2 X_{2t} + \beta_3 X_{3t} + \beta_4 X_{4t} + \beta_5 X_{5t} + \beta_6 X_{6t} + u_t$$

Where: the dependent variable is return on equity (ROE) and return on total assets (ROA). The independent variables (X_{it}) are operating time of the business (X_1), Quick ratio (X_2), Total debt/equity (X_3), Annual net revenue growth (X_4), Asset turnover ratio (X_5), Total consolidated assets (X_6).

3. Results

Source: Synthesis of the research team

Quick ratio (QUICKRATIO): some real estate companies listed on Vietnam stock market have quick ratio with minimum level of 0.0618. This value less than 1 indicates that “some businesses cannot afford to pay their short-term liabilities with their current assets without selling off their inventory. The figures show that the quick ratio of real estate businesses in Vietnam is generally not high.

Total Debt/Equity (DEBTEQUITY): With the mean value of 19,6043 and the variation around the standard deviation of 51,31174, it proves that there are many enterprises with this coefficient greater than 1, that is, The assets of real estate businesses are financed mainly by liabilities. When liabilities account for a high proportion of equity capital, businesses that borrow can be at risk of debt repayment problems. However, besides that, there are also enterprises with total debt-to-equity value less than 1, that is, liabilities account for only a small percentage, enterprises mainly rely on equity. From there, it can be seen that these businesses have less difficulty in corporate finance.

GDP growth: In the period 2017 - 2022, the average economic growth rate reached 5,6940%. During this period, due to the impact of the Covid-19 epidemic, GDP had an unstable growth with the variation of this index around the average value at 2,1592%, however, there was still a point It is positive that Vietnam still maintains a positive economic growth rate during this period.

Enterprise size (SIZE): Most of the listed real estate businesses are large-scale enterprises because real estate is an area that requires larger capital resources than businesses in other fields. These businesses need to spend money on other expensive assets such as land, housing, infrastructure, etc. These assets are mainly long-term investments that can be accumulated over a long period of time year.

3.2. Regression results

3.2.1. Model estimation of factors affecting ROE

Use the Modified Wald test to detect the phenomenon of variable variance. The results show that P-value = 0.0000 (<0.05) shows that the equation has variable variance. To overcome the phenomenon of variable variance of the model, robust technique is used. The results of model testing after error correction are shown in Table 4.

Source: Research team

The estimated results of the model show that the regression coefficient of the DEBTEQUITY variable is statistically significant at 1%; SIZE, ASSETTURNOVER, GDP are statistically significant at 5% level; QUICKRATIO is statistically significant at the 10% level. Thus, the ratio of total liabilities/equity, the size of the enterprise, the asset turnover ratio, GDP, the quick ratio has an impact on the level of profitability ROE.

$$ROE = -53.36338 + 0.2708794*SIZE + 0.3256655*QUICKRATIO + 0.0329167*DEBTEQUITY + 1.69803*ASSETTURNOVER + 29,76312*GDP$$

The SIZE variable is statistically significant at the 5% level with a regression coefficient of 0.2708. This means that, other things being equal, the profitability measured by ROE will increase to 0.2708 units when the size of the business increases by 1 unit.

QUICKRATIO variable, the regression coefficient of the variable has a positive result with a value of 0.3256. The P-value of the variable is 0.091, which means that the QUICKRATIO variable is statistically significant at the 10% level. Prove that, when the

Based on Table 4, the model's estimation results show that the regression coefficients of the variable *SIZE* and *GDP* are statistically significant at 5%; *QUICKRATIO*, *DEBTEQUITY* is statistically significant at the 10% level. Thus, enterprise size, GDP, quick ratio, total debt/equity ratio affect the level of ROA profitability.

$$ROA = -31.55761 + 0.8906429*SIZE + 0.1873439*QUICKRATIO + 0.00747*DEBTEQUITY + 23.81052*GDP$$

According to the analysis results, the variable *SIZE* is statistically significant at the 5% level with a regression coefficient of 0.8906. This means that, in the condition that other factors are constant, the level of profitability is measured by the indicator. ROA will increase to 0.2708 units when the size of the business increases by 1 unit.

For the variable *QUICKRATIO*, the regression coefficient of the variable has a positive result with a value of 0.1873. The P-value of the variable is 0.097, which means that the *QUICKRATIO* variable is statistically significant at the 10% level. Prove that, when the quick ratio of a financial institution increases by 1 unit, the level of profitability measured by ROA will increase to 0.1873 units (with all other factors constant).

With the *DEBTEQUITY* variable, the statistics show that the *DEBTEQUITY* variable has a positive regression coefficient with a value of 0.0074. The P-value of the variable is equal to 0.0067 which means that this variable is statistically significant at the 1% level. That is, the return on equity ROA will increase by 0.0067 units when the total liabilities to equity ratio increases by 1 unit (all other things being equal).

Finally, the *GDP* variable is also considered in the regression analysis. Statistics show that this variable has a positive regression coefficient with a value of 23.8105. The P-value of the variable is 0.01 which means that this variable is statistically significant at the 5% level. This proves that, the level of profitability measured by ROA will increase to 23,8105 units, GDP growth rate increases by 1 unit, provided other factors remain unchanged.

4. Discussion and Conclusion

The results of the study on factors affecting the profitability of real estate enterprises listed on the stock market in Vietnam in the period 2017 - 2022 show that there are 4 main factors affecting the profitability of real estate businesses. Assets include: (1) Enterprise size, (2) Quick ratio, (3) Total debt/equity, (4) GDP growth rate.

In order to achieve the goal of increasing profits, real estate businesses need to increase the size of their businesses, promote equitization, and strengthen the management and effective use of State capital. At the same time, it is necessary to expand the scale of operations and invest in projects with high feasibility and great profit potential, ensure the synchronization between fields of operation, build prestige and strengthen the the trust of customers and the community. However, when deciding to expand, businesses need to identify and understand the general context of the economy in general and the real estate market in particular. Enterprises should only increase their business size when the economy is in a development cycle with many supportive policies for industries to develop at the same

time. On the contrary, when the economy falls into a recession like the present one, the expansion can bring many great risks for businesses such as inability to pay loans on time, increase costs interest rates, etc. Therefore, it can be said that expanding the size of a business is a double-edged sword, used at the right time and in the right way will help the business to grow significantly, but if used at the wrong time, this method can be effective. can cause the whole business to go bankrupt.

Quick ratio is an important indicator to assess the ability of real estate businesses listed on the stock market to pay short-term debts in cash. To improve quick ratios, real estate businesses need to implement a series of financial management measures, including increasing equity, reducing fixed costs, applying risk management tools, etc. financial risk and business optimization. The ratio of total debt to equity is an important indicator in evaluating the performance of real estate businesses. To take advantage of this index's potential, businesses need to ensure the effective use of capital and debt management. at the same time, propose strategies to strengthen business activities and invest in highly profitable projects to reduce this ratio and improve business performance. Only when a balance is achieved between strengthening financial capacity and managing financial risks can businesses develop sustainably and enhance shareholder value in the long term.

FACTORS AFFECTING VIETNAMESE CUSTOMERS' INTENTION TO PURCHASE RECYCLED PRODUCTS

Dr. Nguyen Thi Phuong Linh

linhnp@neu.edu.vn

*Faculty of Business Management,
National Economics University, Hanoi, Vietnam*

Abstract

In the context that Vietnam is moving towards a green and sustainable development strategy, promoting consumers' intention to purchase recycled products becomes even more necessary. Using a combination of qualitative research - in-depth interviews with 10 consumers and quantitative research - a large-scale survey of 587 consumers in the North, Central and South of Vietnam, this study demonstrated that perceived value has a positive relationship with customers' intention to purchase recycled products; perceived safety has been shown to have a greater opposite effect than perceived quality and perceived risk on customers' intention to purchase recycled products. Based on the research results, the author makes some recommendations for state management agencies and enterprises to promote the intention to recycle products of Vietnamese consumers.

Keywords: *Recycled products, sustainable development, Vietnamese consumers*

1. Introduction

Sustainable consumption behavior is the use of goods and services that meet basic needs and provide a better quality of life, while reducing the use of natural resources, hazardous materials, and waste in the life cycle, so as not to jeopardize the needs of future generations (Ofstad, 1994). Sustainable consumption involves satisfying the needs of consumers, while minimizing the negative impacts caused in the exploitation, production and consumption of resources (Cooper, 2013).

The amount of natural resources available on earth is limited and humans are consuming more than they can get back. One way to tackle the problem of overuse of natural resources is to integrate recycled materials into the production process of new products. Recycling is the practice of reusing materials from used products, instead of not using raw materials and turning them into new products of the same quality (Gaur et al., 2017). In addition to conserving the limited and available natural resources of the earth, recycling has a number of other significant environmental benefits including reducing pollution (in water and air), greenhouse gases and waste (Beasley et al., 2014).

Some companies are making efforts to use resources sustainably, such as clothing chain H&M, which aims to use 30% recycled materials in their clothing by 2025 (Hein, 2022). However, current studies show that consumers are willing to pay less for recycled products than for products made from new materials (Pretne et al., 2021), indicating an

increased perceived risk associated with to recycled products (Hamzaoui Essoussi & Linton, 2020). This suggests that it is important to continue to explore the factors that influence consumers' intention to purchase recycled products.

The general trend of the world in the coming time will change from the "brown economy" to "green economy" development model and Vietnam also has a green growth strategy and this is an opportunity to develop the recycled products market. However, Vietnamese consumers currently do not have a sense of environmental and ethical values when buying recycled products.

Therefore, this study will explore the factors affecting the intention to purchase recycled products of Vietnamese consumers, thereby making some implications for state management agencies and enterprises to promote the intention to purchase recycled products.

2. Conceptual Framework and Hypotheses

According to Pearce (2009), recycling is defined as the process by which a used product is broken down into consistent parts, converted into different products or used as raw materials and recycled products are items that are made from materials that are recycled and transformed into new products.

Purchase intention can be defined as an individual's willingness to purchase a particular product or service. Bigliardi et al. (2020) grouped factors affecting consumers' intention to purchase recycled products into three groups: personal-related, product-related, and context-related. Personal-related group consists of structures that explain the values, beliefs, norms, and attitudes that guide an individual's behavior toward a certain intention to act. Product-related groups contain structures that can be traced back to the object of the purchase review. Context-related group an influence the perception of a product. In this study, the author focused on a number of factors related to individuals and products that affect consumers' intention to purchase recycled products.

Previous studies have suggested that perceived value has been developed as an important construct, which has a positive influence on consumers' purchase intention towards environmentally friendly products (Wang et al., 2019). Perceived value refers to the consumer's view of the importance of a particular product or service based on its evaluation of its usefulness (Chen and Chang, 2012). Previous studies have found that perceived value has a significant influence in the customer's decision-making process and in the formation of their purchase intention (Yadav and Pathak, 2017). Therefore, it can be assumed that:

H1. Perceived value has a positive effect on customers' intention to purchase recycled products

Interest in consuming environmentally friendly products (known as "green products") can help consumers build a positive image of recycled products. Reducing waste, reusing waste materials and requiring less energy will create a good product image that can

change consumer behavior and contribute to wider acceptance of recycled products (Hazen et al., 2017). The positive image of recycled products as well as an increasing sensitivity to environmental issues has changed consumer behavior, including increased demand and greater acceptance of recycled products (Tsen et al. 2006) and are willing to pay more for these products (Laroche et al., 2001). Based on the previous findings, the author proposes the following hypothesis:

H2. Product image has a positive effect on customers' intention to purchase recycled products

In the view of some consumers of recycled products, purchasing recycled products is risky, uncertain and unsafe. These problems involve many aspects such as discouraging the production of recycled products; lack of consumer experience of recycled products; lack of knowledge about the safety of recycled products; and the possibility of contamination. The risk that consumers perceive is a deterrent to purchasing recycled products (Agostini et al., 2021). Previous studies of consumer reviews of recycled products have shed light on perceived risks that could hinder adoption of these products (Michaud and Llerena, 2011). As a result, recycled products can create a negative impact on perceived safety, adversely affecting the purchasing process. More precisely, some consumers perceive recycled products made from second-hand, waste, or contaminated materials, reducing their purchase intention (Meng and Leary, 2021). Therefore, the following research hypothesis is presented:

H3. Perceived safety has a negative effect on customers' intention to purchase recycled products

Perceived risk, defined as the perception of loss related to a purchase, is a factor that affects the purchasing process and consumer choice (Mitchell, 1992). Current research shows that consumers perceive green products to be more expensive and lower quality than conventional products (Zeng & Durif, 2019), leading to financial and performance risks. Furthermore, Hamzaoui Essoussi & Linton (2010) found that recycled products have a high functional risk leading to a lower willingness to pay. Based on these arguments, the following hypothesis is formed:

H4. Perceived risk has a negative effect on customers' intention to purchase recycled products

Perceived quality has been found as a factor influencing consumer purchase intention (Dodds et al. 1991). Perceived quality can be defined as an individual's subjective judgment regarding the superiority or excellence of a product (Zeithaml, 1988). Previous research has demonstrated that when a product is recycled, this practice can reduce consumers' expectations of product quality (Lin and Chang 2012; Wang et al. 2013). Furthermore, although some consumers may perceive that recycled products contribute to environmental problems, these products may be of lower quality or more contaminated (Baxter et al. 2017).

H5. Perceived quality has a negative effect on customers' intention to purchase recycled products

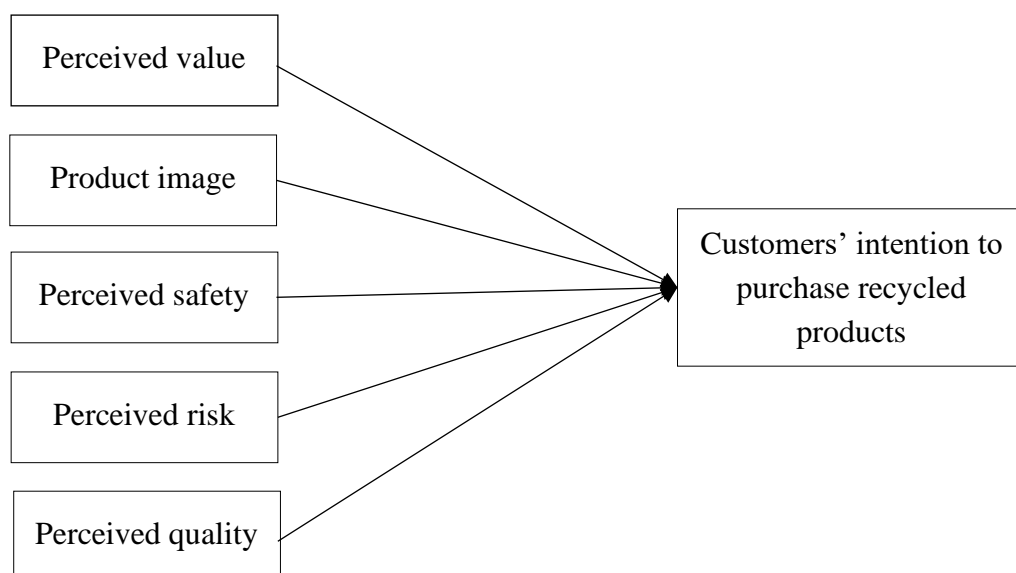

Figure 1. Proposed research model

3. Method

Survey and sample

Qualitative research was conducted through in-depth interviews with 10 consumers in Hanoi. The content of the interview to confirm the appropriateness of the scales and items was included in the questionnaire. Interviews were conducted for approximately 1 hour at a location chosen by interviewees in January 2023.

Quantitative research was conducted through a large-scale survey by random sampling method. The author directly distributed and collected survey questionnaires at three locations: supermarkets, universities and some enterprises in the North, Central and South in February 2023. The authors collected a total of 631 questionnaires. After screening the questionnaires with insufficient information and reliability, 587 questionnaires were selected to serve the quantitative analysis phase (details in Table 1).

Table 1. Characteristics of the sample

Variable	Frequency	Percentage
Gender		
Nam	281	47.9
Nữ	306	52.1
Age		
Under 25	179	30.5
25-40	211	35.9
40-55	115	19.6
Over 55	82	14.0

11-15 million	162	27.6
16-30 million	214	36.5
Over 30 million	65	11.1
Area		
North	218	37.1
Central	119	20.3
South	250	42.6

Analyses

The analysis process includes three main steps. Firstly, Cronbach's alpha and explorative factor analysis (EFA) are implemented to assess the reliability of perceived value, product image, perceived safety, perceived risk, perceived quality and customers' intention to purchase recycled products. Secondly, correlation analysis to assess the relationship between variables. Finally, regression analysis to test hypotheses and assess the level of influence. The above statistical analyzes were performed with the help of SPSS 24.0 software.

Measures

All scales used in this study were adapted from the past researches including perceived value (Chen and Chang, 2012), product image (Luu & Baker, 2021), perceived safety (Luu & Baker, 2021), perceived risk (Wang et al., 2018), perceived quality (Luu & Baker, 2021) and customers' intention to purchase recycled products (Sun et al., 2018). For measuring each construct, five-point Likert scale was used ranging from "strongly disagreed = 1 to strongly agreed = 5.

4. Results

The reliability test was used to confirm whether the determine measures can be employed as representation of the global independent and its sub - variables and global depend variable and its sub- variable. Previous studies have shown that observers with a

small (less than 0.3) variable-to- aggregation coefficient will be excluded and criteria for scale selection when Cronbach's Alpha reliability is greater than 0.6. The larger the Cronbach's Alpha, the higher the internal consistency (Nunnally & Bernstein, 1994). Taken together, six variables in the survey had Cronbach's Alpha ranged from 0.850 to 0.903. All of these values are above 0.6, generally considered to be the higher limit of reliability (Hair et al., 1995). After assessing the reliability of scales by Cronbach's alpha, total of 22 items are used in the exploratory factor analysis (EFA). The results of testing the reliability of scales by the exploratory factor analysis shows that KMO = 0.844, Sig. (Bartlett's Test) = 0.000 < 0.005. The final results of the exploratory factor analysis are presented in Table 2.

Table 2. The results of exploratory factor analysis (EFA)

Variables	Component					
	1	2	3	4	5	6
Intention (INT) $\alpha = 0.870$	0.822					
	0.815					
	0.753					
	0.745					
	0.733					
Perceived risk (PR) $\alpha = 0.903$		0.888				
		0.881				
		0.861				
		0.860				
Perceived value (PV) $\alpha = 0.875$			0.867			
			0.817			
			0.816			
			0.778			
Product image (PI) $\alpha = 0.856$				0.899		
				0.879		
				0.828		
Perceived quality (PQ) $\alpha = 0.867$					0.872	
					0.842	
					0.841	
Perceived safety (PS) $\alpha = 0.850$						0.868
						0.845
						0.834
Cumulative % = 75.068						
Eigenvalues = 1,.371						

Table 3 presents the means, standard deviations and zero-order Pearson correlations of six variables. Perceived value ($r = 0.419$, $p < 0.01$) had proportional relationship with customers' intention to purchase recycled products. Meanwhile, perceived safety ($r = -0.403$, $p < 0.01$), perceived risk ($r = -0.106$, $p < 0.05$) and perceived quality ($r = -0.401$, $p < 0.05$) was negatively related to customers' intention to purchase recycled products. These results provided initial support or rejection for some of the hypotheses

Table 3. Means, standard deviations and correlations

	Mean	Std. Deviation	INT	PV	PI	PS	PQ	PR
INT	3.9370	0.69364	1					
PV	3.6644	0.69755	0.419**	1				
PI	3.6536	0.79961	0.174	0.252	1			
PS	2.4685	0.82774	-0.403**	-0.158	-0.084	1		
PQ	2.4134	0.85074	-0.401**	-0.272	-0.179	0.241	1	
PR	2.6427	0.78758	-0.106*	-0.177	-0.119	0.123	0.179	1

The results of the linear regression analysis show that all hypotheses are accepted ($\text{Sig} < 0.05$), except for hypothesis H2. In which, perceived value has a positive relationship with customers' intention to purchase recycled products ($\beta = 0.302$). In addition, perceived safety has been shown to have a greater opposite effect than perceived quality and perceived risk on customers' intention to purchase recycled products ($\beta = -0.249$, -0.201 and -0.028 respectively).

5. Discussion and Implications

Discuss research findings

This study was conducted to understand the individual and product-related factors that influence customers' intention to purchase recycled products.

Firstly, a significant positive relationship between perceived value and customers' intention to purchase recycled products was confirmed in this study. This result was in line with the findings of past studies (Chen and Chang, 2012; Cheung et al., 2015; Chaturvedi et al., 2020).

Secondly, product images have been shown to have no relationship with customers' intention to purchase recycled products. Some studies such as Luu and Backer (2021) when exploring consumers' purchase intention of rPET bottle-based apparel also agreed with this statement of the study.

Thirdly, perceived safety and perceived quality had a negative effect on customers' intention to purchase recycled products. Authors such as Luu and Backer (2021), Queiroz et al. (2021) also reached the same conclusion in their studies.

Finally, perceived risk, as expected, had a negative impact on customers' intention to purchase recycled products. This was consistent with existing research for other green products, e.g. refurbished products by Singhal et al. (2019); recycled products by Hein (2022).

Implication

In order for consumers to decide to purchase recycled products, state management agencies and enterprises need to join hands to change consumers' perception of recycled products through a number of measures. *Firstly*, it is necessary to improve the production process of recycled products, all stages from input materials to processing need to comply with safety and quality regulations to ensure safety for consumers. *Secondly*, actively communicate about the usefulness, quality and safety of recycled products through a variety of media such as television programs, advertisements, entertainment programs, fairs and exhibitions. In this context, enterprises should not have the idea that recycled products developed from recovered or waste materials would be preferred over new products. In contrast, enterprises need to make recycled products attractive enough to compensate for the low-quality bias associated with products made from scrap in order to compete with new products in the market (Singh and Ordoñez, 2016). Research results have shown that two factors that significantly affect customers' intention to purchase recycled products are perceived value and perceived safety, so state management agencies and enterprises need to focus on these two factors to promote customers' intention to purchase recycled products, thereby contributing to environmental protection and towards a sustainable economy.

Abstract

This study aims to evaluate community-based tourism development activities in Phong Nha -Ke Bang National Park. The research analyzed data collected from 400 residents with a pre-designed survey. The results of the linear regression analysis show that there are 7 factors affecting the development of community-based tourism in Phong Nha - Ke Bang National Park. The most significant factor is the attractiveness of tourism resources and the destination image. The participation of local people also has a statistically significant impact on the dependent variable.

Keywords: *Community-based tourism, Phong Nha - Ke Bang National Park, Tourism development.*

1. Introduction

Quang Binh is famous for its diverse and unique tourism potentials, Phong Nha - Ke Bang National Park has been recognized by UNESCO as a world natural heritage twice and become the most attractive destination of the province. According to Action Program No. 01-CTr/TU on 9/12/2020 on developing tourism to become a strategic industry in the period of 2021-2025 "Exploiting and promoting the potential and advantages of tourism resources. Sustainable tourism development associated with preserving and promoting the national cultural identity, protecting the environment and ecology" of the Standing Board of the Quang Binh Provincial Party Committee. In the past years, Quang Binh has focused on developing community-based tourism (CBT) in the Phong Nha - Ke Bang National Park, as a key factor to improve the efficiency of tourism activities, develop the local economy, towards the sustainable tourism development of the province.

However, up to now, CBT activities in Phong Nha - Ke Bang National Park are generally fragmented, the achievement are not really commensurate with the available potentials and advantages. Although the orientation and planning for CBT development has been implemented, it still lacks a methodical and synchronous approach; CBT products are still monotonous and not competitive and have not really attracted the attention of tourists. According to Quang Binh Department of Tourism, before being affected by the Covid-19

epidemic, the total number of tourists to Quang Binh was 4.985 million, of which, the number of community-based tourists in Phong Nha - Ke Bang National Park only reached 883,640, accounting for 17.7%. In 2021, due to the impact of the Covid-19 epidemic, the inbound market was basically closed from April 2021, the total number of tourists to Quang Binh was 569,826, down 69% over the same period in the previous year and achieved 11% of the plan. In 2022, the total number of tourists to Quang Binh was 2,010,720, 3.7 times higher than the same period in 2021.

With its potentials for CBT development, there have been many studies to develop tourism in Phong Nha - Ke Bang National Park. However, the research mainly revolves around assessing potentials and solutions for sustainable tourism development from the perspective of state management. For CBT, local people are considered as subjects and attracting tourists is one of the goals for tourism development. Therefore, it is extremely necessary to research and develop CBT based on the perspective of local people, and to propose effective recommendations and solutions for CBT development.

2. Conceptual Framework

2.1. Community-based tourism

According to Carard and Paddon (2010), CBT is a type of tourism, in which the community directly owns and participates in management, for the common development goal in the community. Tourism Law No. 09/2017 states that “CBT is a type of tourism developed on the basis of the cultural values of the community, managed, exploited and benefited by the local community”. In this study, the author approaches the concept of CBT from the perspective of tourism activities in which the local community directly participates, exploits and conserves resources, improves skills and knowledge to provide experience and satisfy the needs of tourists.

2.2. Community-Based tourism development

CBT development is an economic and social process based on the active participation of local communities (Jafari et al. (2000). Tourism development may lead to problems for the community, unless there is a clear direction and planning, tourism development will raise awareness for the community about the possible consequences, community opportunities, empowering communities to make decisions, training local communities on governance, providing better technical facilities and services, establishing stronger management mechanism in the community. Bui Thi Hai Yen et al. (2012) argues that CBT development is a way to develop sustainable tourism, in which local communities are directly involved in the development stages of tourism activities.

2.3. Research model and hypothesis

2.3.1. The attractiveness of tourism resources

Tourism resources are natural landscapes, natural elements and cultural values as the formation of tourist products, tourist sites and tourist attractions in order to fulfil tourism needs. Tourism resources include natural resources and cultural resources (Tourism Law

2017). Research on the attractiveness of tourist destinations by Alhemoud and Armstrong (1996) has shown that tourism resources are a factor that build up the attractiveness of destination and attract tourists' attention. Dang Trung Kien (2020) also proved that tourism resources are an important factor creating the attractiveness of tourist destinations and affecting tourism development.

Hypothesis H1: The attractiveness of tourism resources has a positive influence on the development of community-based tourism.

2.3.2. Destination accessibility

Accessibility to a tourist destination is the ability to reach a destination through different aspects. It can be the ability to travel to tourist destination; travel between points within destination or the accessibility to information about the destination... considered as one of the factors that evaluate the attractiveness of a tourist destination. Chi and Qu (2008) study the relationship between destination, tourist satisfaction and loyalty, The results supported the proposed destination loyalty mode (1) destination image directly influenced attribute satisfaction; (2) destination image and attribute satisfaction were both direct antecedents of overall satisfaction; and (3) overall satisfaction and attribute satisfaction in turn had direct and positive impact on destination loyalty.

Hypothesis H2: Destination accessibility has a positive influence on community-based tourism development.

2.3.3. Infrastructure - utilities

Infrastructure - utilities are service elements and facilities located at the destination or attached to the destination, that create favorable conditions for visitors to easily access the destination. Infrastructure - utilities are considered tangible factors in CBT development, is one of the most important factors to attract tourists to a country or a tourist destination (Phuong et al., 2020). Good tourism infrastructure will create favorable conditions to attract more tourists.

Hypothesis H3: Infrastructure - utilities have a positive influence on community tourism development.

2.3.4. Destination image

According to Bui Thi Hai Yen (2012), the more attractive the destination is, the more satisfied visitors will be. Therefore, destination image is considered as a factor that directly affects tourists' satisfaction with CBT destinations. Nguyen Trong Nhan (2013) emphasized that tourism activities in general and CBT in particular have a close relationship with the destination image, taking advantage of the characteristics of destination image can attract more tourists.

Hypothesis H4: The destination image has a positive influence on the development of community tourism.

2.3.5. Local community

In CBT activities, local people play an important role. Their skills, knowledge and attitudes are considered as a supporting tool for CBT development. Attaallah and Al-Ehewat

(2016) approach from the perspective of community awareness of tourism resources and activities, which is the ability to attract more capital for tourism, develop tourism human resources and increase tourism capacity of the community at the destination. Doan Thi Hanh Dung, Tran Thi Thu Ha (2019) also used this factor in terms of the community's attitude and decision-making ability. The authors examined people's attitudes towards promoting, learning to improve skills, being friendly with tourists as well as evaluating decision-making ability through exchange and contribution opinions with stakeholders to jointly make decisions. After reviewing related studies, consulting with experts and from reality in the study area, in this study authors approaches factors in three aspects: skills and knowledge about tourism of local people; local people's awareness and attitudes about tourism and the participation of local communities in decision-making.

Hypothesis H5a: Tourism skills and knowledge of local community have a positive influence on the development of community-based tourism.

Hypothesis H5b: The awareness and attitude of the local community about tourism have a positive influence on the development of community tourism.

Hypothesis H5c: Participation in the decision-making process of local community has a positive influence on the development of community-based tourism.

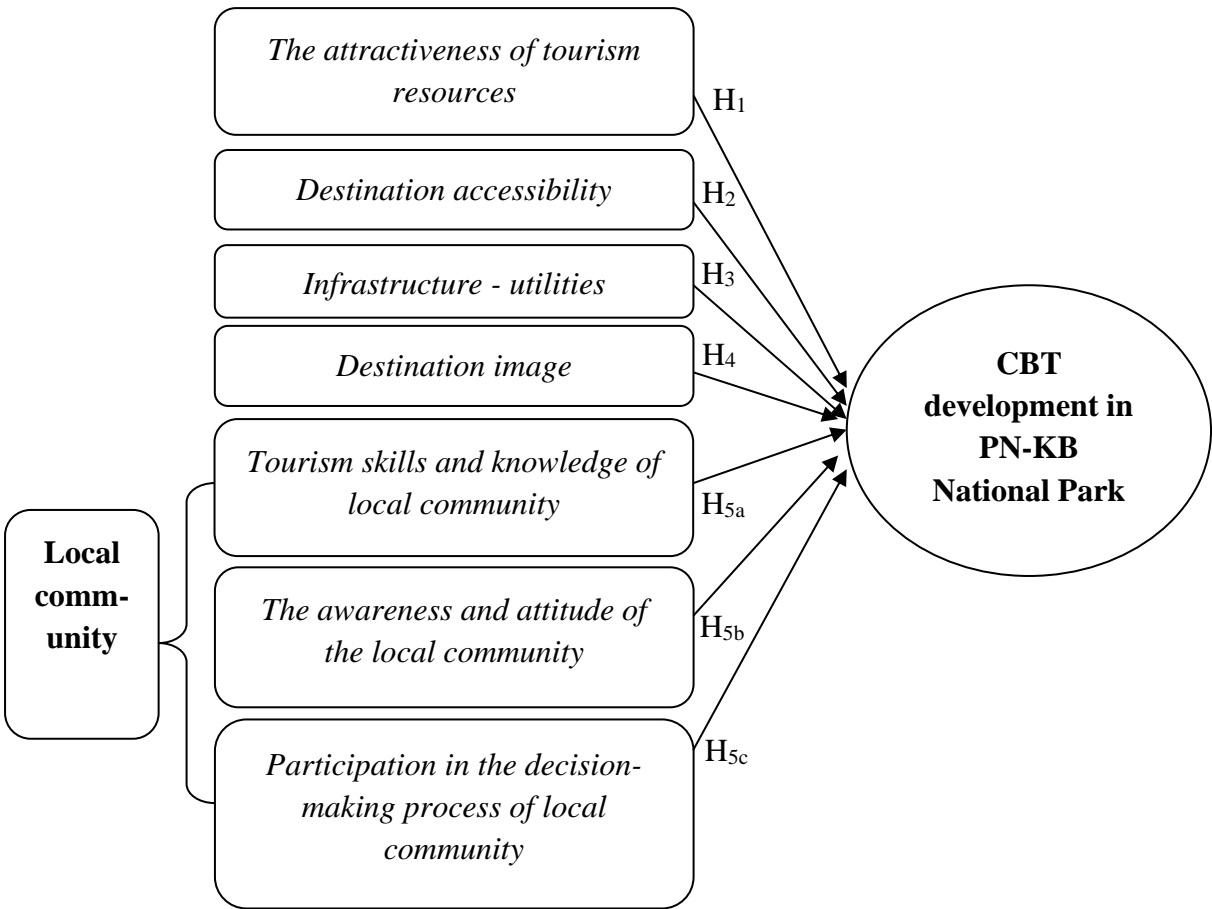

Figure 1. Research model

3. Method

3.1. Data collection and scale development process

The study conducted a survey of local residents participating in CBT activities in Phong Nha - Ke Bang National Park. The questionnaire was designed based on previous studies (Table 1). The study used a 5-point Likert scale for all variables.

Table 1. Variables and references

Variables	Number of Observations	References
The attractiveness of tourism resources (HDTN)	11	Alhemoud and Armstrong (1996); Dang Trung Kien (2020)
Destination accessibility (TCDD)	5	Dwyer and Kim (2003)
Infrastructure - utilities (CSHT)	9	Beerli and Martin (2004), Ha Khanh Nam Giao (2011)
Destination image (MTTQ)	4	Beerli and Martin (2004), Chi and Qu (2008)
Skills and knowledge (KNKT)	6	Nguyen Doan Hanh Dung, Truong Thi Thu Ha (2019); Beerli and Martin (2004)

- Non-Financial aspects	8	Le et al. (2018)

Source: Authors

- Sample size

With a wide distribution space and based on the current scope of tourism development in Phong Nha - Ke Bang National Park, the authors conducted a survey with people living in the buffer zone around the National Park belongs to 3 districts: Bo Trach, Quang Ninh and Minh Hoa and with sample size determined according to the formula of Yamane (1973).

With a suitable error of $\varepsilon = 5\%$ (corresponding to a confidence level of 95%). With the number of households by 2022 in the study area according to statistics is $N = 17,125$ households (Quang Binh Statistical Department, 2022). According to Yamane's formula, the amount of sample to be determined is:

$$n = \frac{17.125}{1 + 17.125 \times (0,05^2)} = 391$$

Thus, the total number of questionnaires is 391. In this study, the authors distributed 450 questionnaires to ensure the research sample size.

3.2. Statistical technique

Data obtained from the official survey was processed by SPSS 22.0. The authors use regression analysis to find out the relationship between the dependent variable and independent variables, to estimate or predict the expected value of the dependent variable when knowing the value of the independent variables. The purpose of this analysis is to consider the level and order of impact of each factor on the development of CBT in the Phong Nha - Ke Bang National Park. The model is as follow:

$$DLCD = \beta_0 + \beta_1 * HDTN + \beta_2 * TCDD + \beta_3 * CSHT + \beta_4 * MTTQ + \beta_5 * KNKT + \beta_6 * NTTD + \beta_7 * RQD + \varepsilon_i. \quad (\varepsilon_i : \text{errors}).$$

Where: Dependent variable: Community-based tourism development (DLCD).

Independent variables (Xi): Attractiveness of tourism resources (HDTN); Destination accessibility (TCDD); Infrastructure - utilities (CSHT); Destination image (MTTQ); Skills and knowledge of local people (KNKT); Awareness and Attitude of Local People (NTTD) and Ability to Participate in Decision Making (RQD).

4. Results

4.1. Community-based tourism activities in Phong Nha - Ke Bang National Park

CBT based on natural resources: focuses on eco-tourism and adventure products, such as visit the cave system; plant and animal species; rivers, streams and natural landscapes in villages. The local residents act as tour guide for visitors, providing information as well as supporting visitors to make their own trip: porting, cooking, technical instruction (for adventure tour).... With a unique cave system, in recent years, Phong Nha - Ke Bang has focused on exploiting adventure tourism products and initially achieved good results. This type of tourism is unique compared to other localities in the country.

CBT based on human resources: focus on exploiting tourism products such as homestay/farmstay; visiting historical and cultural relics, craft villages, traditional festivals... Local people play the role as direct producer and performer, also responsible for guiding activities, providing information for visitors, creating connections between the community and tourists when tourists want to visit or participate in activities of craft villages and community's culture, learn about daily life, customs, beliefs, culinary culture, festivals, folk experiences, housing architecture.

In the period 2018-2022, Phong Nha - Ke Bang National Park welcomed 13,320,720 visitors, the total number of visitors participating in CBT accounted for more than 21.2% compared to the total number of tourists to Quang Binh. In recent years, this proportion has decreased due to the growth of other tourist destinations. However, by 2020, due to the impact of the Covid-19 pandemic, Quang Binh's tourism has severely damaged by the freezing of the international market, and decrease in domestic travel demand. Tourist arrivals to Quang Binh decreased by 63% compared to 2019, CBT visitors in the National Park also decreased significantly (down 64% compared to 2019). Visitors to the area are mostly domestic tourists. In 2022, the total number of tourists to Quang Binh reach 2,010,720, 3.7 times higher than the same period in 2021. In which, international visitors reached 30,787, 5.92 times higher than

the same period in 2021, domestic tourists reached 1,979,933 arrivals, 3.68 times higher than the same period period in 2021 (Quang Binh Department of Tourism, 2018-2022).

Figure 2. Number of visitors to Quang Binh from 2018 - 2022

Source: Quang Binh Department of Tourism

4.2. Cronbach's Alpha coefficient

Before being included in the exploratory factor analysis, the research data would be tested by using the Cronbach's Alpha of SPSS software to check the reliability of the scale. The test results are presented in Table 2.

Table 2. Factors affect CBT development

TT	Factors	Observations	Cronbach's Alpha
1	The attractiveness of tourism resources (HDTN)	10	0,949
2	Destination accessibility (TCDD)	5	0,883
3	Infrastructure - utilities (CSHT)	9	0,948
4	Destination image (MTTQ)	4	0,906
5	Skills and knowledge (KNKT)	6	0,920
6	Awareness and attitude (NTTD)	4	0,926
7	Decision making (RQD)	3	0,949
8	Community-based tourism development (PTDL)	11	0,849
	Total	52	0,933

Source: Data analysis

In Cronbach's Alpha analysis, observed variables with total correlation coefficient < 0.3 will be excluded from EFA analysis. Each component of the factors must have Cronbach's Alpha coefficient > 0.6 . The results of Cronbach's Alpha analysis show that after removing the HDTN11 variable (because it does not satisfy the testing criteria), the remaining values are all > 0.6 and the variable correlation coefficient - the sum of the observed variables are all higher than the allowable standard is 0.3. Therefore, the above scales are all used in the EFA analysis in the next step.

4.3. Exploratory factor analysis (EFA)

In EFA, all observed variables have the lowest factor loading factor of 0.724 and the highest of 0.935, ensuring the requirements in factor analysis. The factor loading coefficients are all greater than 0.5. The scale drawn is acceptable because the coefficient KMO = 0.872 ($0.5 < \text{KMO} < 1$) and the significance level of the Bartlett test = $0.000 < 0.05$, the test has statistical significance and the observed variables. correlated with each other as a whole.

The extracted variance $74.821\% > 50\%$ shows that the extracted factors explain 74.821% of the variation of the data at the Eigenvalue coefficient = 1.465. Thus, all criteria of factor analysis for measuring scale of CBT development in Phong Nha - Ke Bang National Park are accepted in terms of value.

EFA analysis for the dependent variable shows that: All the important variables in the scale of Community tourism development (including 2 groups: financial and non-financial aspects) are converted into a single factor, named the new factor: CBT development.

4.4. Regression analysis

The results of linear regression analysis (Table 3) show that the model has Sig coefficient. F is much smaller than the significance level $\alpha = 5\%$, so the regression model is significant and suitable for the obtained data set. Therefore, the independent variables in the model have a relationship with the dependent variable CBT development. The Durbin - Watson coefficient of the model is 1.787, showing that the model does not have autocorrelation.

Table 3. Regression analysis

STT	Independent variables	Model			VIF
		β	Std. β	Sig.	
	Constant	-0,228		0,000	
1	Destination image	0,242	0,215	0,000	1,134
2	Destination accessibility	0,170	0,150	0,000	1,853
3	The attractiveness of tourism resources	0,250	0,236	0,000	1,210
4	Skills and knowledge	0,158	0,123	0,000	1,450
5	Awareness and attitude	0,177	0,161	0,000	1,172
6	Decision making	0,064	0,066	0,029	1,334
7	Infrastructure - utilities	0,224	0,165	0,000	1,190
R^2		0,771			
Adjusted R^2		0,766			
F		153,077			
Sig. F coefficient		0,000			
Dubin- Watson coefficient		1,787			

Source: Data analysis

In this model, there are 7 independent variables, the results of regression analysis show that the model has statistical significance (adjusted $R^2 = 76.6\%$, $F = 153.077$, $\text{Sig. } F < 0.05$). Based on the results on Table 3, the adjusted R^2 coefficient is 0.766, which means that 76.6% of the variation of CBT development is explained by 07 variables included in the model. With this value in exploratory factor studies, the fit of the model is quite high.

Table 3 shows that all standardized coefficients β are statistically significant > 0 , indicating that the independent variables have a positive impact on the dependent variable of CBT development in the Phong Nha - Ke Bang National Park. This result confirms that the hypotheses stated in the research model are accepted and tested accordingly.

Thus, the model is represented in the form of a linear regression equation with the dependent variable of CBT development as follows:

$$DLCD = -0,228 + 0,250 * HDTN + 0,170 * TCDD + 0,224 * CSHT + 0,242 * MTTQ + 0,158 * KNKT + 0,177 * NTTD + 0,064 * RQD$$

With a sample size of 400 and research in the buffer zone of Phong Nha - Ke Bang National Park, the regression results show that, among the groups of factors included in the study, the factor Attraction of tourism resources (HDTN) has the strongest impact on CBT development with impact coefficient $\beta = 0.250$. The positive impact coefficient shows that the factor Attractiveness of tourism resources has the same and strongest impact with the dependent variable.

The destination image has the second largest impact on the development of CBT with the impact coefficient $\beta = 0.242 > 0$, showing that this factor has a positive impact with the dependent variable.

The third influencing factor on CBT development is Infrastructure - Utilities with impact coefficient (effect coefficient β is 0.224). The following influencing factor is the local community's awareness and attitude factor with a β coefficient of 0.177. The factor Accessibility to the destination has the 5th place with a β coefficient of 0.170. The sixth effect is the local people's knowledge and skills on tourism (coefficient $\beta = 0.158$). Finally, the decision-making ability with a β coefficient of 0.064.

5. Discussion and Conclusion

The study examines the influence of factors on the development of CBT in the Phong Nha - Ke Bang National Park. The results of exploratory factor analysis and linear regression show that the measurement model based on a sample of 400 local residents in the Phong Nha - Ke Bang National Park has theoretical as well as practical significance.

From a theoretical perspective, the study has clarified the impact of 07 factors constituting the development of CBT in the Phong Nha - Ke Bang National Park area, including: The attractiveness of tourism resources; Destination accessibility; Infrastructure - utilities; Destination image; Skills and knowledge of local people; Local people's awareness and attitudes and their ability to participate in decision-making. This is consistent with previous studies by Nguyen Bui Anh Thu et al (2019), Phuong et al (2020). Moreover,

based on the regression value, it shows that the attractiveness of tourism resources is the factor that has the strongest impact on the development of community tourism, followed by the environment of tourism. The regression results also show that the skills and knowledge of the local people, the awareness and attitudes of the local people have a great impact on the development of community tourism.

In practical terms, the research results contribute to improving the understanding of Phong Nha - Ke Bang National Park managers and local people about the importance of factors constituting the development of community-based tourism in the area. In this area, especially skills, knowledge and attitudes of local people in preserving and promoting tourism activities.

As with previous studies, this study also has some limitations. The research model is still limited in that it does not show all the factors that have an impact on tourism development in the study area, the factors included in the study only show more than 76% of the variation of tourism. community tourism development. This is also a suggestive direction for future studies to get more complete results.

MIGRATION IN ASIAN COUNTRIES: EXPLORING THE EVIDENCE FOR THE INFLUENCE OF CLIMATE CHANGE AND SOCIO-ECONOMIC FACTORS

MA. Huynh Hien Hai

haihh.18ae@ou.edu.vn

Ho Chi Minh City Open University, Ho Chi Minh city, Vietnam

Abstract

A new economic force for regional and global cooperation and integration has emerged in the Asian region. For the past three decades, migration in these countries has been a great concern. Although migration for work opportunities has been widely studied, migration resulting from climate change factors, such as temperature, rainfall, and environmental degradation, has mostly been overlooked in the current literature, especially for Asian countries. To address this gap, we conducted a study using the generalized method of moments to investigate the effects of climate change and key economic factors on migration for a sample of Asian countries from 1990 to 2020. Our empirical findings indicate that climate change factors, including temperature, rainfall have a significant impact on migration from these Asian nations. Furthermore, economic fundamentals such as unemployment have reduced migration and GDP per capita lead to the increase of migration at destination over the past three decades. Based on these findings, this paper offers policy implications.

Keywords: *Climate change; Migration; the Asian countries*

1. Introduction

Human beings have been on the move since the earliest times. People move in search of work or economic opportunities, to join family, or to study. Others move to escape conflicts, persecution, terrorism, or human rights violations. Still, other people move in response to the adverse effects of climate change, natural disasters, or other environmental factors. Today, Asia has 85.6 million international migrants by mid-2020, out of more than 280 million international migrants worldwide, this region is second only to Europe. While this is an area that is heavily affected by global climate change (UN, 2020).

Many countries identified as 'climate vulnerable' tend to experience high emigration rates. Therefore, it is critical to consider the existing environment and climate-related evidence when analyzing current migration patterns and estimating future flows. Environmental factors, including those related to climate change and natural disasters, directly and indirectly impact the resilience and vulnerability of individuals, households, and communities, which may lead to migration. Massey et al. (1993) and Stark & Bloom (1985) argue that households employ migration to diversify income streams and guard against climate-related economic uncertainties and shocks. If economic conditions degrade,

households can rely on a stable income stream through remittances from a member residing elsewhere. The self-insurance function of migration is best described when the household members are sent to an international destination where the weather and market conditions are uncorrelated to those at home (Massey et al., 1993). Many studies have looked at ways people migrate, beyond contributing to population increase, have impacted upon environments. These studies look at how migrants use the environment (Begossi, 1999; Curran & Agardy, 2002). Other studies have demonstrated that adverse climatic conditions can indeed increase the risk of international out-migration (Feng & Oppenheimer, 2012; Gray & Bilborrow, 2013; R. M. Hunter et al., 2013; Nawrotzki et al., 2013). However, these studies have predominantly emerged for Latin America, which may be partly explained by this region's unique historical, economic, social, and political context (Kaenzig & Piguet, 2014). In contrast, climate-related economic recessions may reduce the likelihood of international migration and 'trap' people in place (Black et al., 2011). The links between climate, environmental changes and migration are very complex. Environmental migration is a multi-causal and multi-dimensional phenomenon based on a stratified interconnection of economic, political and social factors (governance, policy and access to resources).

Additionally, temperature and rainfall have been widely used in empirical studies on migration at the macro level. For example, Backhaus et al. (2015); Beine & Parsons (2017); Dallmann & Millock (2017); Falco et al. (2018); Jha et al. (2017); Mastrotillo et al. (2016); Mueller et al. (2020); Sedova & Kalkuhl (2020); Sloat et al. (2020); Thiede et al. (2016) use temperature to examine the relationship between migration and climate change. Backhaus et al. (2015); Beine & Parsons (2017); Dallmann & Millock (2017); Falco et al. (2018); Jha et al. (2017); Mastrotillo et al. (2016); Mueller et al. (2020); Nawrotzki & Bakhtsiyarava (2017); Sedova & Kalkuhl (2020); Thiede et al. (2016) use the rainfall to investigate its impact on migration. Besides, Backhaus et al. (2015) and (Marchiori & Cantoni, 2015) suggest that an increase in temperature and precipitation in a sending country is associated with an increase in migration flows to the respective destination country

Our literature review identifies a research gap in the relationship between migration and climate change, including environmental degradation and economic indicators. The gap warrants this study to be conducted because of the following reasons.

First, despite an increasing amount of research, there is still a lack of understanding regarding the connection between the environment and migration and the mechanisms behind it. There are various theories that attempt to explain why and how climate change affects migration decisions. In addition to disrupting livelihoods, particularly for agricultural households that heavily rely on environmental conditions for income, climate change can influence migration through other means. The consequences of exposure to environmental changes can vary significantly across regions based on local agricultural conditions, opportunities for income diversification, and options for adaptation. Furthermore, environmental factors are interconnected and may be correlated with one another both spatially and temporally.

Second, the Asian region is characterized by its diversity. Climate change and environmental degradation is a significant concern, and it has a significant impact on vulnerable Asian countries. The coastlines in this region are densely populated, which makes the countries more susceptible to environmental degradation. Moreover, agriculture is a major source of livelihood, and there is a high dependence on forestry and natural resources. Additionally, the level of extreme poverty remains high. Compared to other regions, the Asian region is more vulnerable to climate change risks due to its dependence on natural resources and agriculture, weak institutions, densely populated coastal areas, and poverty among a considerable proportion of the population. Therefore, the key strategy for sustainable economic growth in this region is adaptation - making necessary adjustments in natural or human systems to respond to actual or expected climatic stimuli or their effects, which helps mitigate negative impacts and exploit beneficial opportunities. Failure to adapt could stall development, particularly in countries that depend on natural resources. Adaptive capacity entails taking a series of actions to change behaviours, shift priorities, produce necessary goods and services, and plan and respond in ways that reduce harmful climate change impacts or transform them into no-regret economic opportunities. Regenerate response.

This study examines environmental, and key economic factors affecting the international migration in Asian countries, such as temperature, rainfall and emission dioxide (climate change factors) and GDP per capita, economic growth, trade openness and unemployment (socio-economic fundamentals). This study focuses on the link between climate change and migration. Migration is considered one of several coping and adaptation mechanisms used by individuals, households and countries. It responds to both push and pulls factors. Changes in the climate (for example, warming temperatures, heat waves, declining rainfall, and CO₂ emission) are part of the push factors because they lead to a deterioration of the environment.

2. Method

This study examines the effects of environmental degradation and socio-economic factors on migration (Mueller et al., 2020; Backhaus et al., 2015; Marchiori et al., 2015). We investigate the impacts of climate change on international migration in Asian countries among five-year data by using the random effect, fixed effect and generalized least squares regression (GLS) for the following model:

$$MIG_i = \beta_0 + \beta_1 TEM_i + \beta_2 RAI_i + \beta_3 CO_{2i} + \beta_4 GROW_i + \beta_5 TRADE_i + \beta_6 UNEMP_i + \beta_7 GDP_i + u_i$$

where: $MIGRATION_j$ is net migration rate by country (per 1,000 population); TEM_i is an average temperature by country (World Bank); RAI_i is Rainfall, mean-temperature by country (World Bank); CO_{2i} is CO₂ emissions (Our World in Data); $GROW_i$ is Economics growth (World Bank); $GROW_i$ is Economics growth (World Bank); $TRADEI$ is Trade openness (Exports and Imports as a share of GDP (%)) (World Bank); $UEMPL_i$ is Unemployment, total (% of the total labour force) (International Labour Organisation - ILO); GDP_i is logarithm of GDP per capita (Current USD) (World Bank)

3. Results

The descriptive statistics of variables are presented in Table 3 below. The temperature (TEM) variable is 18.96°C on average. The highest temperature was in Bahrain at 29.09°C in 2010, while the lowest was in Mongolia in 2010 at -0.42 per cent. For migration, 134.414 per cent came from Qatar in 2010, whereas the smallest migration was 70.79 per cent for Kuwait in 1995.

Table 3. The summary of the descriptive statistics

Variable	Obs	Mean	Std. Dev.	Min	Max
MIGRATION	329	2.2815	15.8831	-70.7870	134.414
TEM	329	18.9602	8.1033	-0.4200	29.0900
RAI	329	6.3024	1.2486	3.2402	8.2651

The Wooldridge and the Breusch-Pagan/Cook-Weisberg tests are used to investigate the autocorrelation and heteroscedasticity in our sample. Results from Table 5 confirm that no autocorrelation is present in our sample. However, heteroscedasticity is present in the regression model.

Table 5. Results from the autocorrelation and heteroscedasticity tests

	Ftest	pvalue	Present autocorrelation	chi2(1)	pvalue	Present heteroskedasticity
	0.068	0.7960	x	383.58	0.0000	✓

GLS is used to deal with situations in which the OLS estimator is not BLUE (best linear unbiased estimator) because one of the main assumptions of the Gauss-Markov theorem, namely that of homoskedasticity and absence of serial correlation, is violated. Therefore, in addition to using re and fe regression, the model also uses GLS technique to overcome. Results is showed in Table 6.

Notes: MIGRATION_j denotes Net migration rate by country, 1990-2020 (per 1,000 population); TEM_i is average temperature by country; RAI_i stands for the rainfall, CO2_i represents the CO₂ emissions; GROW_i denotes GDP growth; TRADE_i stands for the trade openness measured as the sum of a country's exports and imports as a share of that country's GDP (in %); UEMMPL_i represents the unemployment rate (% of the total labour force); GDP_i denotes GDP per capita (Current USD).

In Tables 6, the results show that the TEM variable shows statistical significance and has a positive impact on the international migration in the 47 Asian countries. With an average increase in the international migration of 0.37‰ when the temperature increases 1°C. Similarly, the RAI and UNEMPL variables show statistical significances and have the negative impacts on the migration. Our results indicate that the temperature is associated with increased net migration. Similar results are documented in previous studies (Backhaus et al., 2015; Thiede et al., 2016; Beine & Parsons, 2017; Dallmann & Millock, 2017; Jha et al., 2017; Mastrorillo et al., 2016; Nawrotzki & Bakhtsiyarava, 2017; Sedova & Kalkuhl, 2020; Sloat et al., 2020). However, the RAI variable shows statistical significance and has a positive impact on the unemployment rate. Conversely, a 1% increase in rainfall decreases the migration to 3.73‰. This research also finds that rainfall decreases net migration. The result also aligns with previous studies (Falco et al., 2018; Mastrorillo et al., 2016; Mueller et al., 2020; Nawrotzki & Bakhtsiyarava, 2017). Similarly, when unemployment increases by 1%, migration decreases by 0.46‰. In addition, our empirical result presents that the unemployment is associated with decreased migration. In this case, the international migration rate is calculated by immigration minus emigration per 1000 population. Unemployment can be a cause of impediment to inward migration and promoter of outbound migration in Asian countries. This is consistent with previous theories and research. This result is similar to the GDP variable, when economic growth increases by 1%, migration increases by 3.12‰. Besides that, an increase of GDP per capita is considered a positive signal of migration. The results further support the theories of migration (Harris & Todaro, 1970; Lee, 1966; Ravenstein, 1885).

4. Discussion and Conclusion

Policy implications have emerged based on the findings of this study. First, our findings indicate that international migrants in the Asian countries migrate due to climate change. The increase in temperature or global warming, as well as the change in precipitation, has a great impact on the climate, living and working environment of the people of countries, especially in Asia. Environmental and climate issues are becoming more and more important, unpredictable and have a strong influence on the movement of people around the world, especially in Asia. And one of the best ways, among other important objectives, is to improve environmental quality to attract migrants from other countries and to prevent people from leaving their origin countries.

Furthermore, economic advantages will promote in-migration, while socioeconomic disadvantages will limit immigration and increase emigration. Meanwhile, unemployment is a major barrier to inbound migration and an important driver of outbound migration. Our empirical findings also support the view that high-income level will attract international migration to the Asian region.

Abstract

In rural Vietnam, agriculture is the main source of food and livelihood for many households, making it a central component of programs to reduce poverty and achieve food security. As the sector faces multiple shocks from natural disasters, rural households are forced to develop strategies through diversification to cope with the increasing vulnerability associated with an increase in agricultural production. The study uses data from 344 households from the 2018 Residential Living Standards Survey (VHLSS) dataset. The results of the logit model indicate that the factors of labor force, mean age of labor, education level of labor, participation in party local mass organizations, households' access to credit, and saltwater intrusion have significantly influenced livelihood diversification. In addition, the multinomial logit model also found 13/16 factors included in the model that affect strategies for diversification of livelihoods from agriculture - wage employment, agriculture - non-agriculture, and a strategy that combines all three livelihoods above. In particular, saltwater intrusion has a negative impact on the ability of rural households to diversify. In addition, the study also found an inverse relationship between diversification and poverty. The propensity score matching results show that household participation in livelihood diversification has an impact on increasing household income. This reinforces the hypothesis that diversification contributes to poverty reduction in rural areas of the Mekong Delta. Therefore, in order to secure the capacity of rural households to practice farming along with a variety of income-generating activities to improve the welfare of the rural poor and have a significant impact on poverty reduction, participation in livelihood diversification should be emphasized in development plans.

Keywords: *Multinomial logit model, livelihood-diversification strategies, poverty*

1. Introduction

Natural disasters such as hurricanes, floods, and droughts can directly deplete household resources, push them into poverty traps, increase inequality, and exacerbate the

poverty of those living in poverty. people who are already poor (Bui et al., 2014; Carter et al., 2007). Shocks disrupt household income and consumption flows and cause welfare losses in developing countries (Nguyen et al., 2022). Agriculture-based livelihoods (especially crop production) and smallholder farmers are particularly vulnerable to the effects of shocks caused by natural disasters (Ahmad & Afzal, 2020; Ferdushi et al., 2019), as smallholder farmers mainly rely on crop livelihoods for their livelihood and income (Donatti et al., 2019). For agricultural communities in low- and middle-income developing countries, the impacts of climate change and extreme events are more severe due to a lack of resources, knowledge, services, and resources veterinary and agricultural extension as well as research and technology development (Thornton et al., 2009).

Although agriculture is considered the main source of livelihood in rural areas of developing economies, rural households are increasingly diversifying their livelihood activities to generate income and *better* cope with adverse factors and events affecting agriculture (Ellis & Freeman, 2004). Livelihood diversification occurs when households perform a variety of activities and have social support capabilities to survive and improve living standards (Ellis and Allison, 2004). Diversification can protect vulnerable households from environmental and economic shocks (Eneyew and Bekele, 2012). To cope with the changing situation, reduce losses from agricultural activities, and secure economic and environmental shocks, rural households are adopting diversification strategies from agricultural activities (farming, livestock, and fisheries), non-agricultural activities, transportation and paid activities (Ellis 1998).

In this study, livelihood diversification refers to the efforts of households to find new ways rather than a single activity to raise incomes and reduce vulnerability to livelihood shock. This study examines and evaluates the influence of socio-economic and other factors (including the impact of saltwater intrusion) on the diversification of households' livelihoods. Therefore, this study examines and evaluates the influence of socio-economic and other factors (including the impact of saltwater intrusion) on the diversification of households' livelihoods in the Mekong Delta, Vietnam, a low-middle-income country with a high proportion of the rural population with agriculture as the main source of income (Nguyen et al., 2017) and one of among the countries most affected by climate change (Espagne et al., 2021). The questions of this study include: (i) what is the impact of saltwater intrusion and covariates on the livelihood diversification of rural households; and (ii) how effective is livelihood diversification to reduce rural poverty through increasing household income? The results of this study are intended to provide useful information for policy interventions to support one of the most vulnerable population groups, rural households, especially the poor, to overcome the negative effects of these shocks.

2. Theoretical basis

The Sustainable Livelihoods Framework provides a comprehensive view of the processes that households achieve or fail to achieve in rural livelihood diversification strategies. Livelihood includes a household's capacity, income-generating activities, and holdings that contribute to a means of subsistence (Ellis, 1998). A livelihood is sustainable

when it is able to survive and recover from shocks and stresses and to develop its capabilities and assets, including natural resources, both now and in the future. future. The Sustainable Livelihoods Framework (Figure 1) is useful to determine whether people's livelihoods are sustainable in terms of three main aspects, including livelihood background, livelihood strategies, and livelihood outcomes. Human, natural, physical, financial, and social capital are the five asset classes of a household highlighted by the Sustainable Livelihoods Framework. Households combine these assets with activities and develop a portfolio of livelihood strategies to achieve their livelihood goals, which can be defined as livelihood strategies. Households' choice of livelihood strategy is influenced by asset holdings and external factors such as geographical location and infrastructure (Tesfaye et al., 2011). Livelihood outcomes are benefits derived from livelihood strategies (such as income, food security, poverty reduction, environmental sustainability, etc.). The Sustainable Livelihoods Framework explains the combination of livelihood resources (or accessibility), policies, institutional settings, and processes within a household's ability to decide on the type of strategy or combination of livelihood strategies to pursue and what outcomes can be achieved in the specific context of trends and shocks (Figure 1).

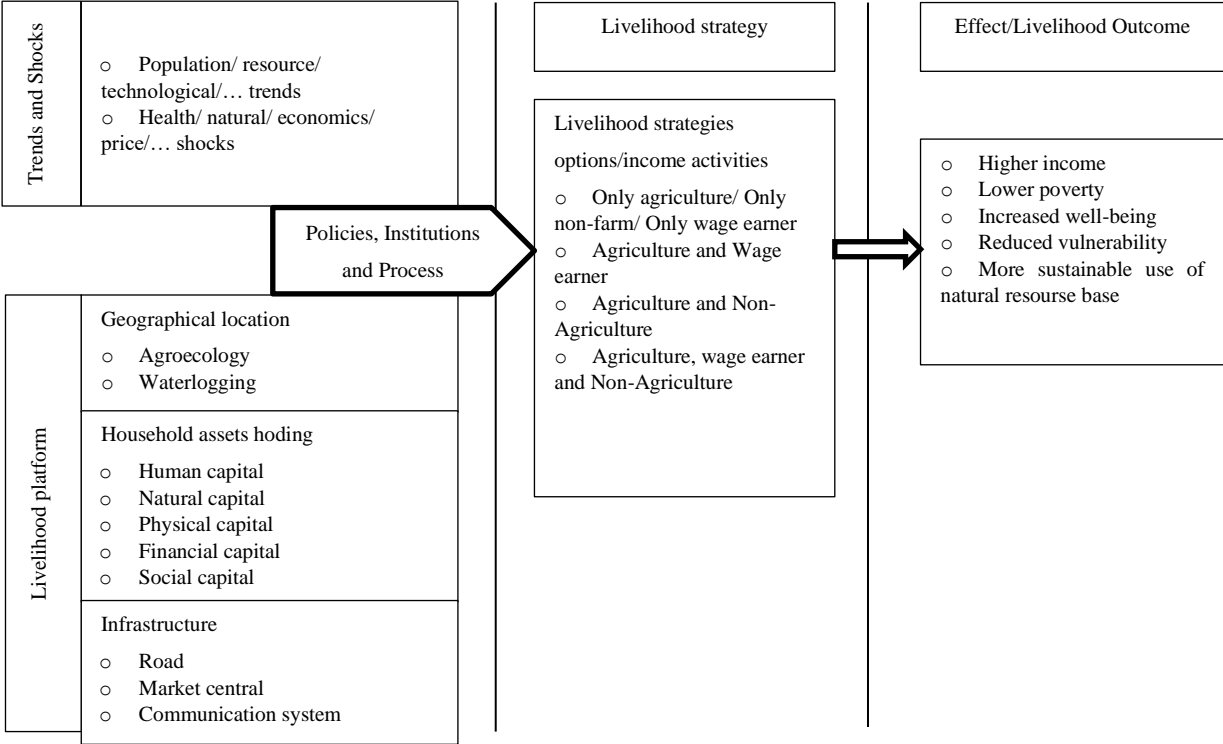

Figure 1. Sustainable Livelihoods Research Framework

Source: Adapted from Ellis (1998) and DFID (1999)

For rural livelihoods, the livelihood strategies of households fall into one of three broad categories: agricultural, wage employment, and non- agricultural. Rural households combine various economic and social activities, thereby building a portfolio of income-generating livelihood activities to meet and enhance sustainable rural livelihood outcomes

(Davis et al., 2010). Households have access to a variety of assets or resources that they can use to engage in agricultural or non-farm activities (including wage employment) or both (Scoones, 2009). According to Ellis (1998), livelihood diversification is a process in which household members develop a diverse set of activities to help them struggle to survive and improve their standard of living. Policy and institutional context refers to the policies and strategies available at the local level related to property rights such as land, community access to agricultural inputs and financial programs, and the availability of other programs that affect the livelihoods of households. Livelihood outcomes are the achievements of livelihood diversification strategies, such as higher incomes, increased welfare, reduced vulnerability, improved food security, and sustainable use of natural resources (DFID, 1999; Ellis, 1998).

3. Method

3.1. Research data

In this study, survey data from 344 rural households in the Mekong Delta region of Vietnam from the 2018 VHLSS dataset is used. Four of the provinces affected by the saline intrusion of the Mekong Delta were selected for the study, including Ben Tre, Tra Vinh, Hau Giang, and Soc Trang. In each province, communes in areas frequently affected by saltwater intrusion and communes in areas not regularly affected by saline intrusion were selected by overlapping the multi-year mean 4 g/l saline boundary map with the commune boundary map of the Mekong Delta provided by the Southern Institute of Irrigation Science in a GIS environment.

3.2 Analytical methods

3.2.1. Estimating factors determining the choice of livelihood diversification for rural households: a binomial logit regression model

The binomial logit model is used to determine whether the household in question is diversifying its livelihood. The binomial logit regression model estimates the probability that a household's choice for livelihood diversification activities can take on one of two values: value 1 if the household chooses to diversify livelihoods and value 0 otherwise. According to Gujarati (2004), the functional form of the binomial logit model is presented as follows:

$$P_i = F(Z_i) = \frac{1}{1 + e^{-(\alpha + \sum_{i=1}^m \beta_i x_i + u_i)}}, i = 1, 2, 3, \dots, m \quad (1)$$

where P_i is the probability that the i -th household engages in livelihood diversification and ranges from 0 to 1; e is the base of the natural logarithm; α is the intercept, β_i is the slope coefficient in the model; and Z_i is the functional form of m explanatory variables (X_i). The slope β_i shows how the log of the odds ratio for a given household engaged in livelihood diversification changes as the independent variables change. If P_i is the probability of a household's livelihood diversification, then $1 - P_i$ represents the probability that a household engages in only one livelihood strategy (no

livelihood diversification). Even so, the interpretation of the log value of the odds ratio is difficult; it only provides the direction of the effect of the explanatory variable on the probability of household participation.

A common alternative to odds ratios is the marginal effect of an explanatory variable based on the probability that Y_i equals 1 versus 0. A marginal effect is defined as the effect of a small change in a variable that explains X_i on the probability $Y_i = 1$, or $\partial P(Y_i = 1|X_i) / \partial X_i$. Marginal effects are less sensitive to changes in model specification than to odds ratios. For the logit model, the marginal effect of an explanatory variable X_i is:

$$ME_i^{Logit} = \frac{\partial P(Y_i = 1|X_i)}{\partial X_i} = \beta_i \times P_i \times (1 - P_i) \quad (2)$$

3.2.2. Estimating the determinants of rural households' livelihood diversification strategies: a multinomial logit regression model (MNL)

The basic assumption of MNL is that, in a given period, a household will choose livelihood diversification strategies that provide maximum utility from expected income household substitution, thus households cannot participate in strategies chosen by households of other groups (Tizazu et al., 2018). For a dependent variable with J livelihood diversification strategies, the j -th livelihood diversification strategy that the i -th household chooses to maximize its utility can take the value 1 if the i -th household chooses the j -th livelihood diversification strategy and 0 if it is not chosen. If a household's utility is measured in terms of realized income, its choice is simply the optimal allocation of available livelihood capital to choose a livelihood diversification strategy that maximizes its usefulness (Brown et al., 2006). The probability P_{ij} that the i -th household with characteristics X_i chooses a livelihood diversification strategy j -th is modeled as a multinomial logit. Therefore, the selection function can be written as follows (Tassew and Oskam, 2001):

$$P_{ij} = \frac{e^{(x_i' \beta_j)}}{\sum_{j=0}^J e^{(x_i' \beta_j)}}, \quad (j = 0, 1, 2, \dots, J) \quad (3)$$

where β_j is the coefficient of covariates between livelihood diversification strategies; X_{ij} are constant covariates between livelihood diversification strategies. Equation (3) is normalized to remove uncertainty by assuming that the probability $\beta_0 = 0$ is estimated to be:

$$P_{ik} = \frac{e^{(x_i \beta'_k)}}{1 + \sum_{k=1}^J e^{(x_i \beta'_k)}}, \quad (k = 0, 1, 2, \dots, J; \beta_0 = 0) \quad (4)$$

According to Greene (2003), the parameter estimates of the MNL model are difficult to interpret; they only provide the direction of the effects of the explanatory variables on the dependent variable, but the model does not estimate the actual size of change or probability.

Instead, the marginal effect measures the expected change in the probability of a given choice being made relative to the unit change in the explanatory variable. Therefore, marginal effects are often inferred to estimate the impact of the independent variables on the dependent variables according to the following probabilities:

$$ME_j^{MNL} = \frac{\partial P_j}{\partial x_i} = P_j \left[\beta_j - \sum_{k=0}^J P_k \beta_k \right] = P_j (\beta_j - \bar{\beta}) \quad (5)$$

Marginal effects measure the expected change in the likelihood of choosing a particular livelihood diversification strategy for a unit change in the explanatory variable. The marginal effect on the explanatory variables shows how $P(Y = 1)$ changes when the explanatory variable changes from 0 to 1, after controlling for other variables (Williams, 2012).

3.2.3. Estimation of propensity score matching (PSM) impact

To analyze the impact of livelihood diversification on household poverty through income, the propensity score matching (PSM) technique was used to generate estimates for the intervention group (households in the diversifying sample, $D = 1$) and the control group (households in the non-diversifying sample, $D = 0$) based on the similarity of observed characteristics. If random livelihood diversification is assigned to a household, we can assess the impact of livelihood diversification on household poverty by comparing the median income average based on diversification and non-diversification. In such a case, the average therapeutic effect (ATT) can be calculated as follows:

$$ATT = E(Y_{1i}|D = 1) - E(Y_{0i}|D = 1) \quad (6)$$

where ATT is the mean therapeutic effect on treatment; D is the core explanatory variable reflecting the diversification of livelihood of rural household i -th; Y_{1i} and Y_{0i} are the incomes of rural households, respectively, when the livelihood diversification sample and the non-livelihood diversification sample.

3.2.4. Dependent variable of the research model

For the binomial logit model, the dependent variable for diversification of household livelihood is a binary variable representing the diversification of the household, taking the value 1 if livelihood diversification and 0 otherwise. For the multinomial logit model, the J group of livelihood strategies of households in this study is classified as follows: $j = 0$ is the household engaged in only one agricultural or wage employment or non-agricultural; $j = 1$ is the household that combines agriculture with wage employment; $j = 2$ is the household combining agriculture with non-agricultural; $j = 3$ is the household that combines agriculture, wage employment, and non-agricultural.

Table 1. Dependent variable used in the livelihood diversification model

Dependent variable	Description of variables	Frequency	Ratio
Binomial logit model (Choosing to diversify livelihoods)			
$Y = 1$	Households with diversification of livelihood	223	64.83
$Y = 0$	Households do not diversify their livelihoods	121	35.17
Multinomial logit model (Choosing between livelihood diversification strategies)			
Y_0 : Non-diversification	Household engaged in only one agricultural or wage employment or non-agricultural	121	35.17
Y_1 : Agri + Wage	Household that combines agriculture with wage employment	122	35.47
Y_2 : Agri + Non-agri	Household combining agriculture with non-agricultural	41	11.92
Y_3 : Agri + Wage + Non-agri	Household that combines agriculture, wage employment, and non-agricultural	60	17.44
Total		344	100.00

4. Results

4.1. Determinants of livelihood diversification in rural households

The binomial logit regression model in Table 2 and the multinomial logit regression model in Table 3 have LR chi2 test values of 96.19 and 170.35, respectively, showing that both models are suitable for analyzing the factors in the choice of livelihood diversification for rural households at the 1% significance level. The estimation results of the binomial logit model show that out of 16 factors included in the model, only 6 have statistical significance, explaining 21.56% of the decision to diversify. In the multinomial logit model, up to 13/16 factors included in the model have statistical significance, explaining 19.15% of the decision to choose livelihood diversification strategies.

Note: ***, **, and * are significant at 1%, 5%, and 10%, respectively.

Labor force of the household: Labor force has a positive impact on the implementation of household livelihood diversification and the choice of a diversification strategy to combine agriculture, wage employment, and non-farm at the 1% significance level. Specifically, if a household has 1 more employee, the household will increase the probability of livelihood diversification by 12.86%, and at the same time, the household will also prioritize the strategy of combining agriculture, wage employment, and non-agriculture 9% more than without diversification. This result is similar to that of Anshiso and Shiferaw (2016) and Amare (2018) and shows that the more members of a household engage in income-generating livelihood activities, the more opportunities for diversification the household will have. Each member can implement different livelihood strategies or jointly implement new livelihood strategies.

Gender of labor: Although the gender of labor does not affect the diversification of household livelihoods, households with more female workers will increase their ability to combine agriculture and non-agriculture is 12.34%. Consistent with Serkalem et al. (2014), this can be explained by the fact that non-agricultural activities in rural areas mostly belong to garment production, agricultural product processing, and retail trade, which are suitable for women's ingenuity gender than men.

Ethnicity: Similar to gender, ethnicity does not determine the diversification of households' livelihoods but reduces the probability of choosing agriculture and wage employment. Accordingly, Kinh households will have less choice in agricultural livelihood and wage employment than Khmer households by 14.82%.

Average age of labor: The average age of labor in the household has a negative impact on the probability of livelihood diversification as well as the probability of choosing a livelihood combining agriculture and wage employment, which are 0.55% and 0.74%, respectively. This implies that people of relatively younger age may be motivated to engage more in agricultural activities and wage employment than in only one livelihood because the younger generation is more educated, therefore more skilled, and has better access to technology. This finding is consistent with the studies conducted by Amare (2018) and Geremew et al. (2017).

Education level of labor: The results show education level of labor has a significant positive impact on the probability of livelihood diversification and the probability of combining agricultural, wage employment, and non-agricultural activities. This means that, other things being equal, a one-step increase in the education level of households increases the likelihood of households engaging in diversification activities by 4.37%, and the combination of agriculture, wage employment, and non-agricultural is 3.36%. The positive impact of education may reflect the fact that more educated workers may be interested in diversification because education can help households engage in more productive activities. The results support the findings of Anshiso and Shiferaw (2016). In addition, Ellis (1998), in his theoretical argument, pointed out that livelihood diversification activities that require more skilled labor will attract people with higher education levels.

Participation in party and mass organizations: Institutional factors that determine households' participation in livelihood diversification activities are related to awareness of households' livelihood activities in organizations, party and union. Becoming a member of these organizations increases the likelihood of participating in livelihood diversification activities by 11.17% while also increasing the probability of choosing a combination of agricultural, wage employment, and non-agricultural. This result is consistent with the study by Kassie et al. (2017). First, the financial constraints of households will be minimized so that they will have the opportunity to engage in non-agricultural activities and generate non-agricultural income when they become members of party organizations and local unions. Secondly, the social capital, market information, and other useful news that households have access to will increase when they become members of the above organizations, so they can grasp timely, effective information for livelihood activities.

Area of arable land: The area of arable land has a positive impact on agricultural-wage employment livelihood at the 5% significance level but has a negative impact on the ability to diversify agriculture, wage employment, and non-agricultural. The positive impact of arable land on livelihood diversification in this study is consistent with the results of Washo et al. (2021). It is possible that households with more land will follow livelihood diversification activities in addition to agricultural production activities; on the other hand, households with larger land areas are expected to lease land to increase their income. In addition, the negative impact of arable land on livelihood diversification is also consistent with the study of Anshiso and Shiferaw (2016). The explanation for this is that when households have more land, it takes more time to cultivate, leading to insufficient resources to combine all three types of livelihoods.

Access to credit services: Access to credit reduces the probability of livelihood diversification of rural households in the study area by 10.63% at the 5% significance level, which is consistent with the studies of Geremew et al. (2017) and Amare (2018). This shows that if the household needs more capital, it will prioritize one type of livelihood to ensure that there are no risks affecting the results of that livelihood activity and, at the same time, to ensure the ability to pay the credit. On the other hand, the possibility of access to credit increases the combined probability of agriculture and wage employment (Anshiso and Shiferaw, 2016). This result reflects the fact that credit services in the short term can solve household budget constraints and thus enhance the capacity of rural households. Households with little land to start and maintain a combination of agricultural and wage employment livelihoods. This shows that better access to credit services accelerates the diversification of rural livelihoods.

Durable assets: Durable assets reduce the probability of choosing a combined agriculture and wage employment by 1.44% at the 10% significance level but increase the probability of selecting the combined agriculture and non-agriculture strategy by 1.55% at the 5% significance level. This result shows that durable assets such as means of transport, means of communication, means of living, etc. support households more when performing non-agricultural activities.

Livestock value: Livestock ownership by households has a significant and positive influence on household choice of agricultural and non-agricultural livelihood strategies at a significance level of 5%. This finding supports Amare's (2018) and may be because owning livestock provides opportunities for other assets, allowing them to diversify their means of livelihood by selling livestock and producing their livestock products.

Distance to district center: The results in Table 3 show that at the 10% significance level, when the distance from the house to the district center increases by 1km, the household increases its ability to combine agricultural and non-agricultural livelihoods by 0.45%, in contrast to the results of Kassie et al. (2017). As mentioned, the non-agricultural activities in the study area are mostly retail trade. Therefore, when households are further away from the center, the efficiency of retail activities will increase due to reduced competition in prices and product categories in the central areas.

Provincial fixed effect: The location of the household is another determinant of livelihood diversification. Households in Hau Giang province will be 13.5% more likely to combine different livelihoods than Ben Tre at the 5% significance level. This can be explained by the fact that Hau Giang is less frequently affected by saline intrusion, so households have more opportunities to implement different livelihood strategies.

Saltwater intrusion: An important thing from the estimates in Tables 2 and 3 is that households in areas frequently affected by saline intrusion will reduce their ability to diversify their livelihoods by 11.91% at a 5% significance level while other factors remain unchanged. At the same time, the probability of implementing the strategy of combining agriculture and wage employment is also reduced by 10.43%, respectively. This is an

important result that shows the negative impact of saltwater intrusion on accessibility, pooling of resources, and activities to diversify livelihood strategies to increase income and stabilize the lives of people in the area.

4.2. The impact of livelihood diversification on rural household poverty

First, the descriptive statistical method combined with the chi-squared test for diversified and undiversified households shows that the two groups have significant differences in the poverty status of households. That means that there is a correlation between poverty and the diversification of rural households' livelihoods. Households that diversify their livelihoods are less likely to fall into poverty than those that do not.

The survey results in Table 4 show that out of a total of 344 households in the sample, the average number of households participating in different livelihood activities is 64.83%, and the remaining 35.17% only participate in one livelihood. In addition, of the total sample of households, 82.85% of households have never fallen into poverty between 2014 and 2018, while 17.15% of households have been poor for at least one year from 2014 to 2018. Results $\chi^2 = 4.71$ in Table 4 show that the difference between livelihood diversification and poverty is significant at the 5% probability level. This implies that most of the rural households in the study area diversify their livelihood sources, and this may affect how closely they link poverty and livelihood diversification.

Table 4. Livelihood diversification by poverty status

Poverty status	Livelihood diversification		Total	χ^2
	Yes (223)	No (121)		
Non-poverty (285)	55.81	27.03	82.85	
Poverty (59)	9.01	8.14	17.15	
Total (344)	64.83	35.17	100.00	4.71**

Note: ** is significant at 5%.

To achieve the stated objectives of the study, this section assesses the impact of diversification on livelihood outcome variables (income) in terms of their significant impact on household participation after pre-intervention differences were controlled. The results of the ATT mean intervention estimate of the propensity score matching method presented in Table 5 provide evidence of a significant impact of livelihood diversification on the income outcome variable. The propensity score matching results show that participation in different livelihood diversification activities has a significant impact on household income at 5%. The average intervention effect of the intervention households indicates that the annual income of participating households is higher than that of non-participating households. Thus, participation in livelihood diversification activities has improved the income of households in the study area. Participation in livelihood diversification has increased the income of rural households in the Mekong Delta by an average of 67.4 million VND per year. This finding is consistent with the study by Abebe et al. (2021) on the positive impact of livelihood diversification on household income.

Table 5. PSM estimation of the impact of saltwater intrusion on rural household income

Variables	Sample	Treated	Controls	Difference	SE	t-test
Change in household income	Unmatched	170437.09	95740.47	74696.62	33634.24	2.22
	ATT	170437.09	103013.20	67405.89	34014.38	1,98**

Note: ** is significant at 5%.

5. Conclusion

Agriculture is the main source of livelihood for rural households. However, due to the impact of trends and shocks on the livelihood platform of households, such as smaller arable land areas and faster population growth, adverse effects due to climate change, and extreme events such as saline intrusion, agricultural production has decreased over time and forced people to look for employment options other than agriculture to achieve food security and reduce poverty in rural areas. The results of the binary logit model show that the factors of labor force, average age of labor, education level of labor, participation in party organizations, local mass organizations, accessibility of household credit, and saltwater intrusion have significantly influenced livelihood diversification. In addition, the multinomial logit model estimate shows that factors such as arable land area and access to credit have a positive impact on the strategy of combining agriculture with wage employment, while ethnicity, working age, and saline intrusion reduce the possibility of choosing this livelihood strategy. Durable assets, livestock value, and distance to the district center will determine the probability of choosing a combination of agricultural and non-agricultural livelihoods, whereas male labor will be less likely to choose this livelihood than female labor. Finally, the ability to combine all three livelihood activities (agricultural, wage employment, and non-agricultural) increases when factors such as labor force size, education level of labor, and participation in party organizations are considered, while land size is the only factor that reduces the ability to choose this livelihood strategy. The propensity score matching results show that household participation in livelihood diversification has a positive and significant impact on increasing household income. At the same time, the study also shows that there is an inverse relationship between diversification and household poverty, which reinforces the hypothesis that diversification contributes to poverty reduction in rural areas of the Mekong Delta.

Based on the results of this study, special attention is needed from governmental and non-governmental agencies to increase access to credit and strengthen credit institutional arrangements in the study areas to improve the livelihoods of rural households. Livestock production is another important factor that positively and significantly influences livelihood diversification strategies. It can be concluded that the increase in livestock stock will provide opportunities for farmers to participate in livelihood diversification options. In particular, farm households can engage in non-agricultural activities by selling their own. Therefore, extension services that regularly liaise with veterinary services and provide necessary training to farmers in terms of animal health, production, and productivity should be sought by local authorities and organizations. NGOs working in the area of particular focus. Besides, expanding and strengthening agricultural extension services for rural households also contributes to creating diversified livelihood activities and improving the livelihoods of rural households.

IMPACT OF THE COVID-19 EPIDEMIC ON REAL ESTATE COMPANIES IN VIETNAM

Dr. Nguyen Thi Tuyet
tuyetnt09@gmail.com

MA. Le Thanh Nhan
lethanhnhan.112vn@gmail.com

Faculty of Economics - Management, Thang Long University, Hanoi, Vietnam

Abstract

The paper used data from financial statements of 41 real estate companies listed on the Vietnam Stock Exchange in the period from the first quarter of 2018 to the fourth quarter of 2021 to examine the impact of the Covid-19 epidemic on the financial performance of these enterprises with the control variables being firm size, liquidity and financial leverage. Research results showed that the Covid 19 epidemic, liquidity and financial leverage have an impact on financial performance. The Covid-19 epidemic has reduced the financial efficiency of businesses compared to the time before the epidemic. Financial leverage also has a negative impact on the financial performance of the business. In contrast, companies with higher solvency have better financial performance. Since then, the article also makes some recommendations to relevant agencies to improve the financial efficiency of enterprises in the industry.

Keywords: *Covid-19, financial efficiency, Real estate, financial leverage*

1. Introduction

The outbreak of the Covid pandemic in China and spreading to other countries around the world has caused negative impacts on the global economy. In Vietnam, the pandemic has disrupted labor sources, reduced industrial output, and disrupted supply chains. The Covid-19 pandemic and lockdown measures have weakened consumption and investment, limiting Vietnam's growth prospects. Before the development of the pandemic, real estate businesses were all affected, although to varying degrees. The group of businesses investing in residential real estate and resort real estate were hit the hardest. The large-scale resort real estate projects in the country were invested and operated by real estate enterprises, which fell sharply; Most resorts have to close or reduce capacity. Besides, real estate investment and rental business activities in commercial centers, office buildings, etc. have also suffered heavy damage due to the business and sales of tenants being delayed or interrupted. The number of new leases is almost nonexistent. Many tenants returned the premises because they did not have enough funds. Most commercial and office leasing establishments must reduce rents during the Covid-19 pandemic.

Given the above facts, this study was conducted to assess the impact of the Covid-19 epidemic and financial leverage on the financial performance of real estate businesses in

order to add more evidence on the impact of the Covid-19 pandemic on the financial performance of real estate companies. The purpose of the paper is to clarify how the Covid-19 outbreak affects the financial performance of real estate companies listed on the Vietnamese stock market. Part 2 of the paper reviews previous studies on the impact of epidemics and corporate characteristics on corporate financial performance. Part 3 is the research method. Part 4 is the estimated results and the last part is the conclusion.

2. Literature review

There are many previous studies that have looked at the effect of dangerous infectious diseases on a company's financial performance. Serious communicable diseases refer to diseases that are highly contagious between people and require extensive health care resources to prevent and treat. For example, Spanish Flu, SARS, MERS, Ebola, Covid19, etc. (Rajakaruna, Liu, Ding, & Cao, 2017) . Therefore, when these diseases emerge, the blockade to prevent the transmission of diseases leads to disruptions to businesses' supply chains, increased job losses, reduced incomes and reduced spending. of consumers. As a result, businesses face a series of macroeconomic difficulties (Fernandes, 2020) . When looking at the impact of the MERS outbreak on consumer spending in Korea, Jung, Park, Hong, and Hyun (2016) found that the epidemic had reduced customer spending, effectively The company's operations were negatively affected due to the decrease in customer demand leading to a decrease in the company's revenue as well as its profit. Aifuwa, Musa, and Aifuwa (2020) studied the impact of the Covid epidemic on the financial and non-financial performance of Nigerian companies. By applying OLS, this study has shown that the Covid epidemic has had a negative impact on both financial and non-financial activities of these companies. However, this study used primary data, regarding the perceptions of business owners and financial analysts, the results are more subjective to that perception.

The Covid pandemic had a major negative effect on the performance of listed Chinese companies. Rababah, Al-Haddad, Sial, and Cherian (2020) found that SMEs are most affected by the pandemic and their data demonstrate that the severely impacted sectors and industries hardest hit by Covid experienced a sharper decline in financial performance than other sectors.

In another study, Khatib and Nour (2021) examined the impact of the Covid pandemic on the financial performance of listed companies in Malaysia. Covid has affected all company characteristics including corporate performance, governance structure, dividends, liquidity and leverage. During the Covid pandemic, leverage and short-term operating ratios increased, but liquidity ratios and profitability ratios of public companies decreased. Liquidity ratio and leverage ratio are not significantly different. However, the short-term profitability and operating ratios of state-owned enterprises differed greatly before and during the COVID-19 epidemic.

In addition, Covid 19 has different impacts on economic sectors. While most industries have been negatively affected by the epidemic, there are also some industries that have benefited from this outbreak. Mobile operators and Internet, electronics, insurance, and

healthcare providers are among the industries that could benefit from social restrictions during the COVID-19 pandemic. Business in the health sector can also make a profit in providing certain types of products such as masks, hand sanitizers, disinfectants, soaps. The food sector is considered a stable business in times of crisis, undergoing only modal adjustments, such as ordering, payment and delivery (Al-Mansour & Al-Ajmi, 2020) .

Financial leverage is also shown to affect the financial performance of the company. There are many studies on the impact of financial leverage on the financial performance of enterprises, but the research results are very different. Financial leverage i.e. the use of debt is considered a “double-edged sword” (Myers, 1995) . High levels of financial leverage can increase the profitability of companies when debt is used properly because firms can enjoy tax shield effects and higher rates of return. from projects with high financial leverage. However, if debt is abused for excessive investment activities, companies may experience reduced profit margins due to high debt burden while the returns generated from investment projects may not. good as expected. Furthermore, high levels of financial leverage increase the likelihood of financial distress that firms face. Previous empirical studies have shown that the impact of the covid epidemic on the financial performance of businesses can be negative or positive. Matar, Al-Rdaydeh, and Odeh (2018) , Salawu (2007) show a negative relationship while Robb and Robinson (2014) provide evidence that there is a positive relationship between leverage and financial performance. of the company. Several other studies have concluded that leverage is a non-statistically significant factor affecting a firm's performance (Gill & Mathur, 2011; Margaritis & Psillaki, 2010) .

Previous empirical studies have shown that there is an impact of the covid epidemic on the financial performance of businesses, these effects can be negative or positive depending on the industry. In addition to the impact of the Covid epidemic, the financial performance of companies may also be affected by other factors of the company, so the specific factors of the companies are controlled to isolate the effects of the Covid epidemic on the financial performance.

According to Afza and Nazir (2007) , different working capital management strategies can affect a company's profitability. An “active” capital management strategy is characterized by investing less in short-term assets, maintaining low inventory levels. This strategy aims to eliminate inventory costs and reduce late payments from customers. As a result, this strategy can allow companies to generate more profits. In contrast, a conservative strategy is characterized by a high investment in short-term assets, including high inventory levels. This strategy aims to respond quickly to fluctuations in customer demand. However, with more inventory, companies incur higher inventory storage costs, which leads to a decrease in their profits (Raheman & Nasr, 2007) . Therefore, there is a trade-off between liquidity and profitability, meaning that the more liquid assets companies hold, the lower their profitability. Ismail (2016) again shows that current liquidity and money conversion

ratios have a significant and positive effect on a company's financial performance (ROA). Chukwunweike (2014) also showed that the current ratio has a positive and significant impact on the profitability of the firm. Thus, liquidity has different effects on the financial performance of the company.

Firm size is also included in the model as a control variable when considering the impact of the Covid outbreak on the financial performance of companies. According to Lee (2009), increasing the size of the company can increase the profit of the company. Firm size can provide economies of scale for firms (Stigler, 1958), since increased size leads to a reduction in the cost per unit of capital. Large companies are more likely to increase financial performance. Larger firms can borrow at lower interest rates and are able to purchase more goods, so they enjoy more trade discounts. In terms of organizational structure with large companies, the level of expertise and specialization of labor is high, large companies can have the advantage of fixed cost-to-product ratio. Large-scale companies also have an advantage in purchasing and using modern machines to improve productivity and product quality.

3. Method

3.1. Data

We collect data from the published quarterly financial statements of 41 companies in the real estate companies listed on the Hanoi Stock Exchange and the Ho Chi Minh City Exchange for the period from the first quarter of 2018 to the fourth quarter to 2021. The data includes the balance sheet and quarterly business results statement of information, these reports provide information on revenue, expenses, and profit, assets and capital of the company. From this information, the author calculates the indicators to measure the variables in the research model. The study used Stata 14 software for processing, descriptive statistics and regression.

3.2. Estimated model

Financial performance is measured by various metrics depending on the purpose of the study. Profitability ratios are common measures used by researchers in financial performance studies (Hart & Ahuja, 1996; Liargovas & Skandalis, 2010; Stanwick & Stanwick, 2000). In this study, the return on assets (ROA) variable is used to measure the financial performance of companies. To assess the impact of the Covid epidemic on the financial performance of companies, the article uses the following research model:

$$ROA_{it} = \beta_0 + \beta_1 * SIZE_{it} + \beta_2 * CR_{it} + \beta_3 * LEV_{it} + \beta_4 * COVID_{it} + \varepsilon_{it}$$

In the above model, ROA (calculated by profit after tax on total assets) is the dependent variable expressing the financial performance of the company. Size (SIZE) is a logarithmic measure of firms' total assets, LEV represents the level of financial leverage (measured as a ratio of debt to total capital of firms), CR is the liquidity variable, which is calculated by dividing total current assets by total current liabilities. The variable COVID is a dummy variable, the quarters in 2018-2019, this variable will take on the value 0, in the quarters in the year 2020-2021, the variable COVID19 receive the value 1.

Table 1. Definition of variables

Variable	Measure
Financial Performance (ROA)	Profit after tax/Total assets
Financial leverage (LEV)	Total liabilities/Total assets
Current ratio (CR)	Current assets/current liabilities
Company Size (SIZE)	Logarithm of total assets
Covid-19 (COVID)	Dummy variable (Get the value 0, if the data is for the period from the first quarter of 2018- quarter 2019. Get the value of 1, if the data is for the period from the first quarter of 2020 to the fourth quarter of 2021)

Source: Author's own compilation

The above model will be implemented according to the following contents: First, the author performs descriptive statistics of the variables and considers whether there is multicollinearity in the model. Then, to estimate the influence of the independent variables on the dependent variable, the author performs Pool OLS, FEM, REM regression and tests to choose the appropriate model, test for heteroskedasticity, autocorrelation of the selected model. If there is a problem of constant variance or autocorrelation, using a general least squares (GLS) model to fix it.

4. Results

4.1. Descriptive statistics

Table 2 provides statistics and describes the variables used in the study. The results of descriptive statistics indicate that the average ROA value of the companies is 1.247113% indicating that the companies can be profitable in the observed time period. The SIZE variable has a mean of 11.87928 and a standard deviation of 0.433882, indicating that there is a difference between companies in terms of firm size. The average short-term solvency ratio CR is 1.764618 which means that on average current assets are 1.764618 times the current liabilities, indicating that companies have enough liquid assets to maintain solvency in the short term. However, the ratio of using debt to total assets of companies in the industry is also quite high, the average debt ratio of companies in the industry is 58.46%.

Table 2. Descriptive statistics of variables

Variables	Obs	Mean	Std. Dev.	Min	Max
ROA	656	1.247113	3.123971	-7.53025	36.75923
SIZE	656	11.87928	0.433882	10,60239	13,04361
CR	656	1.764618	3.359327	0.15305	45.46892
COVID	656	0.5	0.500382	0	1
LEV	656	0.584595	0.226383	0.013013	0.991878

Source: Author calculated from Stata 14

4.2. Regression results

To estimate the impact of Covid on the financial performance of companies, it is first necessary to see if there is multicollinearity in the model. The phenomenon of multicollinearity occurs when there is a linear relationship between the independent variables in the model, making the regression estimates less accurate, the confidence intervals for the regression coefficients are also wider. the significance and effectiveness of the model. Therefore, it is necessary to conduct multicollinearity testing to have reasonable remedies to increase the efficiency of the model. To consider whether the collected variables have multicollinearity phenomenon, we check the variance exaggeration factor VIF.

Table 3. Results of multicollinearity test

Independent variables	VIF	1/VIF
LEV	1.37	0.731447
CR	1.28	0.782615
SIZE	1.19	0.840321
COVID	1.02	0.983819
Mean VIF	1.21	

Source: Calculation from Stata14

The results of testing by Stata 14 in Table 3 show that the VIF variance magnification coefficient is very small, from 1.02 to 1.37 are all less than 2, showing that these independent variables are not closely related together, the model does not have multicollinearity.

The results of the Ftest in Table 4 show that the fixed effect model is non-zero, so it is necessary to continue the Hausman test to select the appropriate model. The Hausman test results show that the FEM model is a suitable model for the study.

Conduct tests to evaluate whether the built FEM model contains defects. The Wald test results show that the FEM model has variable variance. The Woodridge test results show that the FEM model does not have autocorrelation. Therefore, in order to overcome the phenomenon of variable variance, the FGLS estimation method (feasible generalized least squares estimate) was chosen for the regression.

Table 4. Estimated results

	Pool	REM	FEM	FGLS
SIZE	0.368	-0.244	-3,255***	0.368
	[0.293]	[0.443]	[0.946]	[0.292]

Wooldridge test	Prob>chi2 = 0.0944			

Source: Author calculated from Stata software

The estimation results from the estimation model with the FGLS method show that the regression coefficients of financial leverage, liquidity ratio and the Covid epidemic are all statistically significant, except for the variable of firm size.

The liquidity variable has a regression coefficient of 0.188 and has statistical significance at 5%, showing that liquidity has a positive impact on corporate financial performance. Thus, the efficiency of scale has been clearly demonstrated in the real estate industry. Larger asset size has contributed to increased profits for businesses. This result is similar to the results shown in the studies of Kipsha (2013) , Pouraghajan et al (2012) and Gatsi, Gadzo, and Kportorgbi (2013) .

The coefficient of the Covid variable is negative and statistically significant at 5%, showing that during the epidemic outbreak, the financial performance of real estate enterprises decreased compared to the previous time. This can be understood because during the epidemic period, many regulations on isolation have restricted the movement of people. Real estate rentals and sales declined. As a result, the revenue of businesses decreased sharply, leading to a decrease in profits.

The leverage ratio also has a regression coefficient that is negative and statistically significant at 5%, showing that firms with high debt ratios have lower financial performance. This is understood that high debt is accompanied by an increased cost of capital, the financial performance of the business will decrease.

5. Conclusion

By using quantitative methods, the above analysis has shown that factors such as business size, financial leverage and the Covid epidemic have an impact on the financial performance of real estate enterprises. The application of the feasible generalized least squares (FGLS) estimation method has overcome the variable variance so that the estimated results are reliable and unbiased.

The research results have shown that the solvency of enterprises has a positive impact on the financial performance of the enterprise, financial leverage has a negative impact on the financial performance of the enterprise, the Covid-19 epidemic. outbreaks also reduce the financial performance of enterprises.

Through the above research results, some recommendations can be made for related subjects. Firstly, businesses need to increase their solvency, improve their reputation in the market and have a sustainable development orientation. When the solvency is greater, the business will have a higher reputation. Second, companies should adopt an equity-based business model, improve equity financing ratios, and optimize corporate capital structures. In addition, these findings have important implications for policymakers, governments, banks, regulators and the State Bank must combine to address financial and regulatory impacts. economy of the Covid 19 crisis. In such a context, it is very important to provide financial support to companies or to support and enact certain policies, such as tax breaks, to help them alleviate the negative effects of COVID-19. This also has implications for the need to devise comprehensive policies to address the adverse impact of such crises in the future.

Abstract

The research is a sociological study that aims to study the experiences and characters of Karen entrepreneur farmers in northern Thailand through the concept of the entrepreneurial farmer in an agrarian society. Research fieldwork was conducted between August 2020 and March 2021 at two Karen villages, Tamma and Phoenix villages (pseudonym), in Omkoi district, Chiang Mai province, Thailand. These villages were revisited again during January and February 2023. The qualitative data was collected from ten case studies. Four case studies are community leaders, six case studies are Karen entrepreneur farmers from both villages. The research findings indicate that, since the 2010s, some Karen farmers transformed into highland entrepreneur farmers depending on different backgrounds and experiences. They also have performed as the highland entrepreneur farmers into seven characters. There are (1) diversity of economic activities, (2) desire to be free, courage to venture and invest, and give priority to profit and loss, (3) systematical thinking, (4) dependence on social relationships, (5) business risks insurance, (6) innovative creation based on highland resources, (7) dependence on online marketing.

Keywords: *Entrepreneur farmer, Highland agriculture, Karen, Thailand*

1. Introduction

Since the 2010s, entrepreneurship in the agricultural sector and entrepreneurial farmer potential development have been officially placed important as a new form of Thailand's economic structure policy (Office of the National Economic and Social Development Board, 2011; Office of the National Economic and Social Development Board, 2022). The Thai government has worked at full capacity to develop and support the new generations to be entrepreneur farmers or smart farmers in their farmlands. Entrepreneurial training, giving funds, and entrepreneurial research are arranged by government sectors, for example, Department of Livestock Development, Department of Agriculture Extension,

Agricultural Research Development Agency, and universities. At the same time, the format and procedure of Thai entrepreneur farmers and smart farmers have been presented in different channels, such as handbooks, brochures, websites, and multimedia.

Although entrepreneurial farmer development has been formally supported through the Thai government's policies, it is missing from the highland context of Tamma and Phoenix villages (pseudonyms), Omkoi district, Chiang Mai province. After the late 1980s, commercial plants, such as tomato, chili, cabbage, and pumpkin, have been supported and grown in the villages. Most villagers became Karen farmers¹. They grew and traded those commercial plants to lowland merchants. The farmers got a small share from the merchants. For over four decades, even though Karen farmers in the villages have been professional farmers in growing commercial plants, they are still poor due to the fluctuation of crop prices. Supporting and training Karen farmers to be entrepreneurs by the government and other organizations have never happened. Consequently, many Karen farmers in the villages need to find new jobs and move to the lowland. This situation is like the results of many studies. A great number of studies show that most ethnic people, particularly new generations, have tended to immigrate from highland to lowland to find jobs and accumulate funds. The migration of ethnic groups to lowland areas has been derived from two conditions: (1) push factors (development policies, infrastructure development, invasion of commercial plants, loss, debt, poverty, escape from strict traditions; (2) pull factors (differences between rural and urban, cash requirement, educational opportunities in urban) (Thammabandit, 1993; Srisuko & et.al., 2005; Surarerks & et.al., 2008)

According to supporting and training entrepreneurship in Thailand's agricultural sector, Karen farmers in the highland villages have never been paid attention to and supported by the government. Entrepreneurship promotion and training have barely appeared in Tamma and Phoenix villages, Omkoi district, Chiang Mai province. In the past decade, most villagers did not have any chance to train and develop entrepreneurial skills. The quantitative data analysis from the study of Rugchat, Towthirakul, and Saramas (2022) concluded that over a decade (from 2009 to 2019) Karen farmers in Tamma and Phoenix villages had never received any training and support from the government to be entrepreneurs. This study also indicated that most Karen farmers in the villages, more than fifty percent of farmers, did not have entrepreneurial skills and mindsets, particularly creativity, off-farm working skills, risk insurance, finding benefits from different sources, and finding new information. In fact, most villagers are still poor farmers. They cannot transform themselves to be entrepreneurs. According to the problem situation, however, some Karen farmers in the highland villages can transform themselves to be entrepreneurs. Thus, this research article aims to identify the characters of Karen entrepreneur farmers in Tamma and Phoenix villages, Omkoi district, Chiang Mai province through the concept of an entrepreneurial farmer. It also discusses how some Karen farmers can transform themselves to be entrepreneur farmers and what are characteristics of Karen entrepreneur farmers.

¹ Karen is an ethnic group. Most of them scatteringly live in many highland villages in northern Thailand.

2. Method

This research aims to study some background and experiences of six case studies of Karen entrepreneur farmers. It also indicates the characteristics of Karen entrepreneur farmers in Tamma and Phoenix villages, Omkoi district, Chiang Mai province, through the concept of the entrepreneurial farmer. From a sociological perspective, in 1958 the concept of entrepreneurship was mentioned through the study of *Protestant Ethic and the Spirit of Capitalism* by Max Weber. In this study, he defined an entrepreneur as a personal charisma. From Weber's perspective, entrepreneurship was the ability to manage a business and control people. He also explained that the Protestant ethic could support and develop people to make benefits and work hard (Weber, 1958; Swedberg, 2000). Latterly, sociologists and historians brought the idea of entrepreneurship to study the changing of rural and peasant societies. In the same direction, they explained that ethnic groups, minorities, and rural people could become to be entrepreneurs and entrepreneur farmers. Moreover, they had outstanding characteristics different from urban entrepreneurs (Aldrich and Waldinger, 1990; McElwee, 2008; Kahan, 2012, Satayanuruk, 2017).

From Gerard McElwee's viewpoint, the term "entrepreneur farmer" is defined as a farmer who can develop and has entrepreneurial skills. Their farmland can be adapted to do many kinds of activities, such as agriculture, tourism, and service. Thus, they have to do both on-farm and off-farm activities. Entrepreneur farmers have more flexible and creative thinking. The motivation of entrepreneur farmers depended on pull factors, such as the need for freedom and security (McElwee, 2008: 471). In addition, highland entrepreneur farmers are defined as those who can make a profit by collecting agricultural products and selling them to markets, while at the same time, they and their household members still work on the farm. Highland entrepreneur farmers are creative persons. They also can create innovative ways to develop business, while can maintain connections in both vertical and horizontal dimensions (Rugchat, 2018: 129 - 130). In the highland context of Thailand, the study of Rugchat, Saramas, Ruamsap, and Thongsrikate (2021) explains that highland farmers can be developed and transformed themselves to be entrepreneur farmers through three stages: upstream (raising awareness of their own potential), midstream (developing entrepreneurial skills of farmers), and downstream (creating marketing channels).

2.1. Data gathering

This research is a sociological study that aims to study the experiences and characteristics of Karen entrepreneur farmers. In-depth interviews with ten case studies (four community leaders and six Karen entrepreneur farmers) were applied to study Karen entrepreneur farmers in Tamma and Phoenix villages. In addition, the researchers also place importance on the Facebook fan page for recommending products and services of some Karen entrepreneur farmers. The research data collecting was divided into three periods: (1) literature reviews and contact with the community leaders were conducted between August - October 2020; (2) the in-depth interview with ten case studies was conducted between November 2020 - March 2021; (3) two villages revisited and studying the Facebook fan pages did from January to February 2023.

2.2. Study areas and population

Two study villages, Tamma and Phoenix (pseudonym), Omkoi sub-district, Omkoi district, Chiang Mai province, Thailand, are Karen (*Pwo* Karen) villages. They are in a highland area along the 1099 Hot-Omkoi main road, around 170 kilometers south of Chiang Mai City. The north of villages connects to Hot district, Chiang Mai province, while the south is close to Tung Loi village, a Karen village, Omkoi sub-district, Omkoi district, Chiang Mai province (figure 1). In 2021, Tamma village had a population of 335 households, 847 people, while Phoenix village had a population of 329 households, 1,023 people (Community Development Department, 2023).

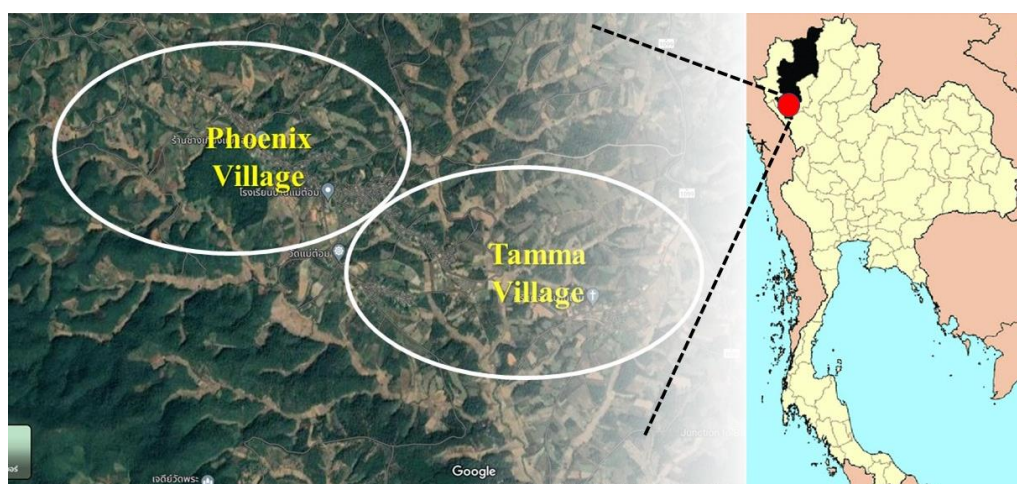

Figure 1. Location of Tamma and Phoenix villages, Omkoi district, Chiang Mai province

3. Results

The research findings can be divided into two parts: (1) the background and experiences of Karen entrepreneur farmers; (2) the characters of Karen entrepreneur farmers.

3.1. The background and experiences of Karen entrepreneur farmers

The findings from quantitative data of the study of Rugchat in 2021 show that the most representative household samplings, 63 households, or 56.80 percent, are female. According to all household samplings, the research found that the most representative household samplings, 48 household samplings (43.20 percent) were aged between 30 - 39 years old, followed by 29 household samplings (26.10 percent) were aged between 40 - 49 years old. Most household samplings, 77 households (69.30 percent), graduated from elementary and high school levels, while 27 households (24.30 percent) had never graduated from any levels (Rugchat, 2021).

According to a great number of Karen farmers in the villages, this research shows examples of six case studies of Karen farmers in Tamma and Phoenix villages - Mr.Song, Mr.Prasob, Mr.Boon, Mr.Sing, Mrs.Kai, and Mr.Thep² - who can transform themselves into

² All case studies' names and the name of someone who was mentioned in this article are pseudonyms.

highland entrepreneur farmers. Experiences of case studies are significant conditions to support Karen farmers to become entrepreneur farmers. In order to understand the transformation to entrepreneur and entrepreneurial characters of case studies, this article will indicate the experiences of Karen entrepreneur farmers case by case.

Mr. Song: From a peddler in the city to a Karen entrepreneur farmer in highland

Mr. Prasob: A highland farmer and seedling wholesaler

Mr. Prasob was 40 years old. Due to his health problems, Mr. Prasob had transformed himself into an entrepreneur farmer since 2014. During 2015 - 2016, apart from the health problems, he strongly desired to be self-employed by starting a seedling business in the village. Mr. Prasob had savings enough to invest in a seedling wholesaler. He built a seedling wholesaler on the land near the Omkoi district office. With two pickup trucks pawns and his savings, Mr. Prasob got approximately 200,000 baht. He spent this capital to build a seedling wholesaler and compile various kinds of seeds, for example, tomato, chili, pumpkin, and eggplant. He learned how to plant seedlings methods by peeping at other seedlings wholesaler owners and remembering the plant methods. In addition, his seedlings business also depended on the support of his sister, who had a chemical fertilizer shop and knowledge of agricultural chemicals used. At present, not only Mr. Prasob is a seedling wholesaler owner, but he also grows in-season rice, macadamia, cultivated banana, and dragon fruits. For making more profits, he sometimes processes cultivated bananas into sweet banana crisps.

Mr. Boon: Broker and transporter of tomato fruits to local warehouses

Mr. Boon was a 49 years old Karen entrepreneur farmer in Phoenix village. He owned three pickup trucks, one tractor, and a Sport Utility Vehicle (SUV). In late 1995, Mr. Boon became a broker and transport tomato fruits to local agricultural product warehouses. At that time, he was just a tomato peddler. He traded tomato fruits to many local merchants. Until 1995, he knew Jae Nam, a female local merchant, who was the biggest local tomato trader and was generous. He was impressed with her and agreed to support Jae Nam as a broker, who collected tomato fruits from tomato farmers for Jae Nam. The tomato trading business of Jae Nam was successful and smoothly conducted. Mr. Boon gained the trust and support of Jae Nam. At the same time, he also learned more about tomato trading methods, investment, and trading plans from Jae Nam. In 2015, Mr. Boon was a broker of Jae Nam, transported tomato fruits from farmers, and grew tomatoes by himself. From 2016 to 2017, he was a seedling wholesaler owner and a tractor driver to gentrify the farmlands of Karen farmers in Phoenix village and nearby villages. In order to increase income, Mr. Boon got an extra income from farmland gentrification of at least 30,000 baht per month. From 2018 until now, he has opened a small garage to repair all pickup trucks of Karen farmers in Phoenix village and nearby villages.

Mr. Sing: Thinker and innovator for growing high-value crop

Mr. Sing was a 33 years old Karen entrepreneur farmer. In 2003, after graduating from junior high school, Mr. Sing decided to find a new job in the city. He used to work in

a noodle shop employee and a gas station laborer in Bangkok. After that, he moved to work in Chiang Mai City as a laborer in an agricultural products warehouse. In 2012, Mr. Sing came back to Phoenix village and grew tomatoes on his farmland. In 2019, due to tomato prices falling, difficulty growing, and high levels of chemical use, he stopped growing tomatoes and changed to growing macadamia. In order to learn about macadamia growth, Mr. Sing searched much information about macadamia on social media and various kinds of websites on his smartphone. Then, in the earliest stage, he borrowed approximately 500,000 baht from his family members and close friends to invest in the macadamia business. To promote his macadamia, word-of-mouth advertising to teachers and government officers was applied to selling macadamia fruits. He expected that these customers will support and widely advertise his macadamia. One year later, macadamia advertising and promotion through social media - Facebook page - have played an important role for trade his macadamia products. From 2022 until now, Mr. Sing has launched a small modern coffee shop in Phoenix village. It also has been promoted on social media, a Facebook page. On the Facebook page, not only his coffee shop shows many beverages and desserts, but it also has presented beautiful and modern shop decorations.

Mrs.Kai and Mr. Thep: A Karen entrepreneur farmer family in Tamma village

Mrs.Kai and Mr. Thep are a couple. At present, Mrs.Kai was 39 years old, while Mr. Thep was 45 years old. Mrs.Kai graduated master's degree from a public university, while Mr. Thep graduated from high school with non-formal education. They helped their parents to grow tomatoes since childhood. After Mrs.Kai and Mr. Thep got married in 1999, they built a small grocery store in Tamma village. It was away from the main road around 500 meters. Mrs.Kai and Mr. Thep owned approximately 20 *rai*³ of cultivated area. Even though they worked on their farmland as farmers, they also owned a grocery store, sold fertilizers and agricultural chemicals, and traded gasoline to Karen farmers in the village. Due to an interesting in trade, in 1998, Mr. Thep began to start his business by buying the land and opening a small grocery in Tamma village. At the same time, he still grew tomatoes in his farmland. He thought that he could make more income together by growing tomatoes. Moreover, Mr. Thep also could estimate the situation and prices of agricultural products. Thus, he could accurately calculate the growing and harvesting periods of many commercial plants. Mrs.Kai could create, invest, and process agricultural products. For example, in late 2020, Mrs.Kai invested to buy an oven and a vacuum sealer for processing and packaging dragon fruits into a new product. She got these ideas from websites and social media. At present, this family (Mrs. Kai and Mr. Thep) has done many jobs. There are growing commercial plants (in-season rice, tomatoes, dragon fruit, macadamia, rambutan), grocery store owners, selling fertilizer and agricultural chemicals, trading gasoline, and selling agricultural equipment.

3.2. The characters of Karen entrepreneur farmers

By the research findings, Karen entrepreneur farmers in the highland villages can be categorized into seven characters as follows:

³ 1 *rai* = 0.14 acre

1) Diversity of economic activities

Karen entrepreneur farmers must do both on-farm and off-farm activities. For making more profits and capital accumulation, they will try to work many jobs and invest in many businesses. Not only plant various kinds of plants (in-season rice, tomatoes, pea eggplant, macadamia, bananas, etc.), but Karen entrepreneur farmers also trade many kinds of products. It differs from Karen farmers who invest particularly in growing commercial plants. Table 1 shows the economic activities (on-farm and off-farm) of six Karen entrepreneur farmers during 2019 - 2020.

Table 1. The economic activities of six Karen entrepreneur farmers during 2019 - 2020

Karen entrepreneur farmer	On-farm activities	Off-farm activities
Mr. Song	<ul style="list-style-type: none"> • growing in-season rice • growing tomatoes • growing pea eggplant • growing cultivated banana • growing organic tomatoes 	<ul style="list-style-type: none"> • grocery store owner • trade gasoline • selling chicken manure
Mr. Prasob	<ul style="list-style-type: none"> • growing in-season rice • growing macadamia • growing cultivated banana • growing dragon fruit 	<ul style="list-style-type: none"> • selling commercial plant seedlings • processing bananas and selling sweet banana crisps
Mr. Boon	<ul style="list-style-type: none"> • growing in-season rice • growing tomatoes 	<ul style="list-style-type: none"> • a broker of a local merchant • a tractor driver • a tomato transporter
Mr. Sing	<ul style="list-style-type: none"> • growing in-season rice • growing macadamia 	<ul style="list-style-type: none"> • processing, packaging, and selling macadamia
Mrs.Kai and Mr. Thep	<ul style="list-style-type: none"> • growing in-season rice • growing tomatoes • growing dragon fruit • growing macadamia • growing rambutan 	<ul style="list-style-type: none"> • grocery store owner • selling fertilizer and agricultural chemicals • trade gasoline • selling agricultural equipment

2) Desire to be free, courage to venture, invest, and give priority to profit and loss

In fact, most Karen entrepreneur farmers desire to be free. They don't want to be employees or laborers. For example, Mr. Prasob gave priority to free. He desired to own a business (seedling business) and be self-employed. Similarly, because Mr. Song didn't want to be a laborer and wanted to have free time, so he decided to resign from the company and start his own business later. In addition, the courage to venture, invest, and give priority to

profit and loss become the crucial characteristics of Karen entrepreneur farmers. For instance, Mr. Song started his business as a peddler by buying many instruments and a new pickup truck. Due to seeing the business opportunities, Mr. Sing ventured to borrow a lot of money from kinships and close friends in the village to start the macadamia business.

3) Systematical thinking

Currently, systematical thinking is an important skill and character of Karen entrepreneur farmers. The systematical thinking of Karen entrepreneur farmers here means two thinking methods: (1) calculation and analysis; (2) a full cycle of systematical thinking. In the case of Mr. Thep, who was satisfied to trade since childhood, he could calculate and analyze trends of agricultural products in the future. Mr. Thep precisely calculated that in the future his grocery store's area has become the best location for trade and transportation. Moreover, he also analyzed that rambutan was effectively grown in highlands. It will be a proper commercial plant to grow in the highland villages. Likewise, Mr. Song analyzed that pea eggplant was a proper commercial plant in a highland village because it yielded in summer and without high investment.

Besides, the full cycle of systematical thinking has obviously appeared in the cases of Mr. Boon and Mr. Sing. Mr. Boon has imaged the system of tomato trading (tomato seedling - tomato growing - harvesting - transportation). In the beginning, he started his business as a tomato transporter and a broker of Jae Nam. Then, he launched economic activities related to tomato trading, such as seedling wholesaler owner, tractor driver, and garage owner. While Mr. Sing has managed macadamia trading with the full cycle of systematical thinking by considering about growing, processing, selling, and promoting.

4) Dependence on social relations

Social relations have become an important condition for Karen entrepreneur farmers. For example, Mr. Prasob has applied kinship (his sister) to support agricultural chemicals knowledge. Moreover, during the labor shortage, his sister has become a laborer for helping him in processing cultivated bananas. In the case of Mr. Boon, the relationship and trust between Mr. Boon and Jae Nam are important factors to support Mr. Boon's businesses. Many times, Jae Nam has often supported Mr. Boon with funds, knowledge, cooperation, and business opportunities. Similarly, the growth of the macadamia business of Mr. Sing obviously happened through kinships and close friends in the village. Namely, at that time, his cousins and close friends gave loans of around 500,000 baht to support Mr. Sing's business.

5) Business risks insurance

Despite without savings in the banks, most Karen entrepreneur farmers have planned for the risk insurance, if they lose money. From Karen entrepreneur farmers' perspectives, doing various businesses both on-farm and off-farm is the business risks insurance. Income gained from many kinds of businesses is risk insurance. At the same time, they also have food security by growing in-season rice and local food around the villages. In addition, the research result also found modern business risk insurance in the highland village. Deposit

money in banks and life insurance become the new methods in highland areas. For instance, similar to entrepreneurs in the cities, Mrs.Kai and Mr. Thep, the prosperous Karen entrepreneur farmers, have risk insurance by depositing savings in commercial banks and doing life and health insurance with insurance companies.

6) Innovative creation based on highland resources

From the Karen entrepreneur farmer viewpoint, Karen ethnic identity has been utilized for trading. For example, in Mr. Song's case, because most Karen people live in the highlands, the Karen ethnicity of Mr. Song was applied to sell boiled local corn or mountain corn. In addition, Karen entrepreneur farmers have depended on the advantage of highland resources and the environment to create unique agricultural products. For example, Mr. Sing depended on the highland environment to grow macadamia (a perennial plant) instead of growing tomatoes. Not only Mr. Sing has shown the macadamia plant as a high-value crop, but he also has indicated environmental conservation, reduction of agricultural chemicals, and soil and nature restoration of macadamia. While Mrs.Kai has grown dragon fruits in the village and tried to create them into dried dragon fruits, new local innovation, with drying and new packaging.

7) Dependence on online marketing

After the internet and online communication systems spread throughout Omkoi district, smartphones, which are connected to the internet system, have played an important role in the businesses of Karen entrepreneur farmers. From Mrs.Kai's perspective, the internet system (via a smartphone) was the new channel to search for useful information. For business development, Mrs.Kai has searched for various data from many kinds of websites via her smartphone, such as cropping information (dragon fruit, tomatoes, rambutan), and processing of agricultural products. Youtube is a favorite website of Mrs.Kai to search for new information, interesting points, and different news. Not only the internet can support Karen entrepreneur farmers in searching for useful data, but it also is an effective instrument to create online marketing. Mr. Sing, a young Karen entrepreneur farmer, has given priority to the internet system and online marketing. He has used social media and online applications, for example, Facebook and Line, to contact and communicate with macadamia traders. Currently, macadamia products' Mr. Sing has been created and promoted on an online marketing channel via a Facebook page under the name "Omkoi Macadamia". He now is a creator and administrator of this Facebook page. Similarly, Mrs.Kai has applied the Line application to sell her dragon fruit product.

4. Discussion and Conclusion

The construction of entrepreneurship of Karen farmers in Tamma and Phoenix villages depended on many crucial conditions, such as the background, knowledge, experiences, mindset, and vision of Karen farmers. In this article, Karen entrepreneur farmers' characters differ from the definition of McElwee (2008) and other scholars. Not only Karen entrepreneur farmers have many economic and entrepreneurial activities, such as nonfarm working, flexible and innovative activities, depending on pull factors, and use

the farm's resources, Karen entrepreneur farmers in highland villages need to depend on social security, social network, innovative creating based on their environment, culture, wisdom. Thus, the research findings have shown Karen entrepreneur farmer's characteristics into seven points: (1) diversity of economic activities, (2) desire to be free, courage to venture and invest, and give priority to profit and loss, (3) systematical thinking, (4) dependence on social relationships, (5) business risks insurance, (6) innovative creation based on highland resources, (7) dependence on online marketing.

Acknowledgement

The researchers would like to thank a research fund from the Faculty of Liberal Arts, Maejo University, Chiang Mai, Thailand. We also thank the case studies (four community leaders and six Karen entrepreneur farmers) who spent a lot of time answering many questions.

Abstract

This study estimates and tests the factors affecting urbanization in provinces/ cities in Vietnam in the period 2010-2021. The results show that Vietnam's urbanization rate increases with population density; gross domestic product (GRDP); tourism revenue; investment capital in the province/ city; Industrial production index; the percentage of trained workers over 15 years old; Provincial Competitiveness Index (PCI) increased. Meanwhile, the number of enterprises is negatively correlated with the urbanization rate and the number of cities is not significant for the improvement of the urbanization rate in Vietnam. This result can provide recommendations for the Vietnamese 2 government in setting goals and policies to improve the urbanization rate in Vietnam.

Keywords: *influence, urbanization rate, improvement*

1. Introduction

The process of urbanization is an opportunity for the Government to organize and re-plan the operation of cities and residents. Accordingly, areas with potential for economic development, cultural development and social development will be planned according to a modern system, areas lack of economic conditions or low population density will be adjusted with suitable industries and project to increase development opportunities in the future. Urbanization in a positive direction will promote economic growth and social development of urban and peri-urban areas. According to The World Bank, there are many examples of developing countries focusing on building and completing institutions and policies to promote urbanization and sustainable urban development that have created impressive economic development based on urbanization such as China and Taiwan in 1950, Korea in 1970, Southeast Asian countries such as Singapore in 1970, Thailand in 1960. Since then, many scientific works have been published, many seminars related to the factors affecting

urbanization in a country such as Anett Hofmann and Guanghua Wan (2013); research papers on the process and development of urbanization such as Henderson (2003), Moomaw and Shatter (1996); etc. In general, these studies refer to the main factors that can affect urbanization rate such as Gross domestic product (GDP), Gross national income (GNI), import-export rate, population density, and Foreign direct investment (FDI). Those are all core values within an economy that have been proven through real-life studies to affect the rate of urbanization. However, along with the development of science and technology and human resources nowadays along with The Fourth Industrial Revolution (4IR), the rate of urbanization in each country depends on both macro factors and micro factors. These factors are intertwined and complement each other in the process of urban development today.

Since the reform and opening up, Vietnam's urbanization level has increased rapidly. Especially in recent years, the development is even faster and the urbanization average annual growth rate has represented an increase of 2.8% (Vietnam Statistical Yearbook 2020), making it one of the fastest urbanizing countries in East Asia. By 2021, the statistics of the General Statistics Office have shown that the national urbanization rate has reached about 38.1%, has now officially entered the period of strong development and is in the process of transition, vertical development from increasing urbanization speed to improving urbanization quality.

Along with the importance of urbanization in the Industrial Revolution 4.0, required studies of the factors affecting the urbanization process in Vietnam. However, current studies have only mentioned the issues of urbanization in Vietnam, research on sustainable urban development and policies to promote the increase of urban proportions. For example Tran Thi Lan Anh (2013) mention the reality of urbanization in Vietnam, the current challenges currently; Dao Hoang Tuan (2009) in the book talks about some theoretical and practical issues for a sustainable development of urban areas. In addition, there are a number of research papers focusing on specific regions such as the research paper of Prof. Dr. Hoang Ba Thinh (2014) in the article "Urbanization and urbanization management in sustainable development in the Central Highlands", Nguyen Quang Giai (2017) in the research: "Binh Duong's urbanization process and the selection of a sustainable urban development model"; etc. In general, these studies has been very successful in presenting the current status and evaluate the impact of urbanization on the surrounding environment and development policies. However, there has not been a scientific study about factors that play the decisive role in the urbanization process in Vietnam. Meanwhile, the Industrial Revolution 4.0 is taking place more and more vigorously, and Vietnam is increasingly infiltrating the process of international economic integration, which requires the Government to have sharper policies to develop the economy towards the strategy of 2030, with a vision to 2045. With the aim of achieving that goal, understanding the core causes affecting the process and rate of urbanization in Vietnam is of top importance.

The measurement and study of the factors that robustly affect the urbanization rate in Vietnam is of great significance in finding basic solutions to limit the negative change towards building and developing an economy, helping the Government and policymakers

make better decisions, meeting the requirements of the new industrial revolution, and improving academic understanding of the urbanization and the origin of the increase in the rate of urbanization. Upon that, our group of students chose the issue "Factors play a decisive role in the process of urbanization in Vietnam." as the subject of this scientific research.

2. Theoretical basis

2.1. Related concepts

From the perspective of social and economic management, an urban area is defined as an area with a high density of people living and mainly operating in the field of non-agricultural economy, it is the economic, cultural and political center of an area having a role in promoting the social and economic development of a country or a territory or a locality, including inner cities and suburbs of a city; inner and outer towns of the town; towns, with a population of 4,000 people or more, an average population density of 2,000 people/km² or more, of which over 65% are employed in the non-agricultural sector.

2.2. Factors affect economic growth

Krugman's research (1991) set the foundation on factors and conditions for the population to be concentrated in one area instead of spreading over several areas. However, both endogenous models of city size and core and periphery models provide little insight into the determinants of a country's total urban population. Nevertheless, the first idea of urbanization has gradually formed from the factors of production conditions, population concentration has been expanded to factors of economic growth, science and technology.

The table below shows some previous research models related to urbanization rate:

Table 1. Summary of experimental research models

STT	Author/ year	Variable affecting urbanization and measurement methods	Research model
11	Pandey (1977)	<ul style="list-style-type: none"> - Population density= Population / Area (person/km²) - Income per worker = Total income of all employees/ Number of employees - Literacy rate = Literacy population/ Population*100% - Population growth = (Total population in current year - total population in previous year)/ Total population in previous year*100% 	OLS
22	Moomaw and Shatter (1996)	<ul style="list-style-type: none"> - GDP per capita = GDP/ population - Urban concentration (the proportion of urban population in cities is greater than 100,000). - Urban priority (proportion of population in largest cities). 	OLS

STT	Author/ year	Variable affecting urbanization and measurement methods	Research model
33	Gene Hsin Chang and Josef C.Brada (2006)	- Rate of industrialization= Industrial production rate/gross domestic product of a country - Foreign Direct Investment (FDI)	OLS
44	Anett Hofmann and Guanghua Wan (2013)	- Economic growth= (current year GDP - previous year's GDP)/ previous year's GDP*100% - Education is calculated based on three main indicators: the proportion of children attending school, the proportion of the population over the age of 25 with the highest degrees, and GDP per capita. - Rate of industrialization = Ratio of industrial production/gross domestic product of a country.	OLS
55	Michel Dimou and Alexandra Schaffar (2014)	- Gross Domestic Product (GDP) - Export rate = (Export value/ Production value)*100%	SAR, SEM
66	Yingchun Yang, Jianghua Liu, Yutao Zhang (2017)	- Economic growth = (current year's GDP - previous year's GDP)/ previous year's GDP*100% - GDP per capita = GDP/ population - Urbanization policy is calculated by two factors: • Urban land use ratio: This ratio represents the urban land area compared to the total area of an area. • Urban management index: This index shows the level of effectiveness in managing urban-related issues such as security, traffic, environmental sanitation, land resource management, planning Urban Development.	FEM, OLS, REM
67	Yuan Zhang and Guanghua Wan (2017)	- GDP per capita = GDP/ population - Total population - Trade openness = Total export value/ Total production value * 100%	OLS

Source: Synthesis of the research team

3. Method

To study the factors affecting urbanization, we analyze according to panel data and based on the premise model of Moomaw and Shatter (1996). Moomaw and Shatter (1996) modeled and considered a range of determinants (not limited to GDP per capita, rate of industrialization, production and export orientation, education) and political aspects). In addition, Moomaw and Shatter further researched the comparison of the relationship of the factors telling about the rate of urbanization and city concentration. The authors have consulted the above model and also learned and proposed a few other important variables.

3.1. Secondary data collection method

Collecting secondary data at relevant agencies such as the General Statistics Office, People's Committee,...

- Vietnam Statistical Yearbook 2010-2021
- Vietnam import and export report 2016-2021
- Statistical report of 63 provinces and cities in Vietnam
- Summary of socio-economic criteria for the period 2016-2021

3.2. Methods of synthesizing and researching in-depth documents

- Collect documents, search for information in related books, search on the internet all documents related to the problem to be researched.

- Refer to the results of relevant previous scientific studies, analyze the data and prerequisite documents on the topic of urbanization in Vietnam in the period 2010-2021, articles and research articles on urbanization, legal documents, urban and economic policies, etc.

- A system of available discrete data documents on the natural and social characteristics of Vietnam. Current status of urbanization, influencing factors and other documents related to the topics covered.

3.3. Quantitative research

The study uses panel data regression model, applies Pooled OLS, FEM, REM, FGLS techniques to evaluate the aggregate effects of independent variables on the dependent variable. The study sample includes 63 provinces, with a total of 756 per year-over-year observations for 12-year table data for the period 2010-2021. Based on the above theoretical basis and on the basis of a number of criteria considered urban, the model of estimating and testing the factors affecting the urbanization rate has the following specific form:

$$\text{LnTyleDTH}_{it} = \beta_0 + \beta_1 * \text{DNHD}_{it} + \beta_2 * \text{DTDV}_{it} + \beta_3 * \text{MDDS}_{it} + \beta_4 * \text{SoTP}_{it} + \beta_5 * \text{GRDP}_{it} + \beta_6 * \text{LnDTDL}_{it} + \beta_7 * \text{LnVon}_{it} + \beta_8 * \text{LnChisosxCN}_{it} + \beta_9 * \text{LnTyleLDQuadaotao}_{it} + \beta_{10} * \text{LnPCI}_{it} + e_{it}$$

Where subscript i denotes 63 provinces of Viet Nam; t denotes year, detailed measurement of variables is shown below:

Table 2. Interpret the variables included in the model

Variable	Description	Unit
Dependent variable		
TyleDTH	Urbanization rate of provinces in Vietnam (63 provinces) in the period 2010-2021.	%
Independent variables		
DNHD	Number of enterprises operating in provinces in Vietnam (63 provinces) in the period 2010-2021.	number of business
DTDV	Revenue of the service industry in the provinces in Vietnam (63 provinces) in the period 2010-2021.	billion Vietnam dong
MDDS	Population density of provinces in Vietnam (63 provinces) in the period 2010-2021.	person/km ²
SoTP	Number of cities under provinces in Vietnam (63 provinces) in the period 2010-2021.	number of city
GRDP	Gross regional product in Vietnam at constant prices in 2010 (63 provinces) in the period 2010-2021.	billion Vietnam dong

4. Results

The following regression results from Stata software have given the results of estimating factors affecting the urbanization rate of provinces and cities in Vietnam.

4.1. Descriptive statistics

Table 3. Descriptive statistics for the variables used in the study

Variable	Observation	Mean	Standard deviation	Minimum value	Maximum value

Source: Results of the research team estimated from Stata

The urbanization rate (TyleDTH) has an average value of 34.14016%, the lowest is Bac Giang province in 2010 is 9.66% and the highest is Da Nang City in 2017 is 87.62%. Gross regional domestic product (GRDP) has an average value of 274,861.73 billion VND, the lowest is Lai Chau province (19,676.38 VND billion, in 2010) and the highest is Ho Chi Minh City (991,424.1 VND billion in 2020). The population density has an average value of 481.6311 (people/ km²), the lowest is Dien Bien province (42 people/ km², in 2010), the highest is Ho Chi Minh City (4476 people/ km² in 2020). The number of operating enterprises (DNHD) with an average value of 8,558,378 enterprises is the lowest in Bac Kan province (399 enterprises, in 2010), the highest is Ho Chi Minh City. HCM (268465 enterprises in 2021). Service revenue (DTDV) has an average value of 204,137.1VND (billion), the lowest is Son La province (63195 billion VND in 2010), the highest is Ho Chi Minh City (709,963.2 billion VND in 2021). Tourism revenue has an average value of VND

1.08,486 (billion), the lowest is Bac Kan, Dien Bien, Son La, Lai Chau provinces (0 billion VND, in 2010), the highest is Ho Chi Minh City (107487,018 billion VND in 2019). The number of cities with an average value of 1.0873866 (cities) is lowest in Binh Phuoc province (0 cities in 2010-2018), the highest is Quang Ninh (4 cities in 2012-2021). Industrial production index (Chisosxcn) has an average value of 123.5762 % the lowest is Bac Kan province (70.96%, in 2010) the highest is Thai Nguyen (345.8185%, in 2018). The proportion of trained workers with an average value of 170.5431 (1000%), the lowest is Dong Thap province (100.47886%, in 2010), the highest is Hanoi (845.3292% in 2021). The provincial competitiveness index (PCI) has an average value of 55.82017%, the lowest is Dien Bien province (42.12% in 2012), the highest is Quang Ninh (75.09% in 2020). Capital investment (Von) has an average value of 4.41e+07 (billion VND), the lowest is Kon Tum province (6.98e+05 billion VND in 2010) and the highest is Ho Chi Minh City (2.17e + 10 billion VND in 2020).

4.2. Correlation analysis and linear multi-additive testing

Table 4. Correlation matrix

	GRDP	DNHD	DTDV	MDDS	SoTP	Ln (Chisosxcn)	ln(DTDLD)	Ln (TyleLD quadaotao)	Ln (Von)	Ln (PCI)

Table 4.2 shows the correlation matrix between variables in the model. The magnitude of the correlation coefficients between the independent pairs of variables is less than 0.8 except for 8 pairs of variables with very high correlation coefficients, greater than

0.8, which can occur multicollinearity in the model. The results of multicollinearity test by Variance Inflation Factor-VIF according to Table 4.3 show that the VIF coefficients except for the DTDV variable with $VIF=11 > 10$ (or $1/VIF = 0.090935 < 0.1$) occur severe multicollinearity; the rest of the variables all have a VIF coefficient between 1 to 10 (or $1/VIF > 0.1$), means there is a slight multicollinearity phenomenon, which can be accepted

Table 5. Multicollinearity test results

Variable	VIF	1/VIF

Source: Results of the research team estimated from Stata

Due to different methods, the estimation results of each model are also different. To select the suitable model, the study conducts the Breusch-Pagan Test (xttest3) to choose between OLS and FEM/ REM and the Hausman Test to choose between FEM and REM. The Hausman test gives results of Prob > chi2 <0.05, so it rejects the H₀ hypothesis, therefore, the FEM model is suitable and reliable. We went on using the FEM model to

assess the impact of independent variables on the dependent variable. To test whether the model has a serial correlation phenomenon, the author used the Wooldridge test. The test results show that the model has the phenomenon of autocorrelation. To fix the above phenomenon, we used the FGLS model to increase the stability of the research model. The model estimation results in table 4.4 show that many variables are marked as expected.

Performed investment (LnVon): having a positive mark as originally expected, with a significant level of 1%, indicates that if investment rate increases by 1%, the urbanization rate will increase to 0.102%. This is easy to explain because when investment increases, it often leads to the establishment of new businesses, which can create new job opportunities. These job opportunities can attract people from rural to urban areas in search of better job opportunities, leading to an increase in population density in urban areas and leading to an increase in urbanization rates.

Tourism revenue (lnDTDL): has positive effect on urbanization rate, as expected, with the Cronbach's Alpha of 1%, when tourism revenue increases by 1%, it will cause the urbanization rate to increase by 0.152%. The rapid increase in tourism revenue contributes to the increasement of the contribution of the service sector to the structure of the economy. Development of the service industry is an important driving force for the implementation of industrialization and modernization goals. Along with the development of tourist cities, all local residents can be involved in tourism business and service activities, thereby contributing to improving the living standard of indigenous people, as well as changing the economic appearance of the whole region. Therefore, tourist urban development is identified as a central issue in the tourism and economic development strategies of many countries around the world.

Industrial production index (LnChisosxCN): bears a positive sign similar to the initial expectation, with the Cronbach's Alpha of 1%, when the index of industrial production increases by 1%, the urbanization rate will increase to 0.096%. There is plenty of evidence that when the index of industrial production increases, it leads to an increase in urban rates: industrialization can create new jobs in the manufacturing sector, jobs in the industrial sector can pay more than other agricultural or rural jobs, etc. Wage differences encourages people to move to urban areas. Moreover, industrialization can stimulate the development of infrastructure, such as roads, bridges and public transport, which can make urban areas more accessible and attractive to citizens.

Proportion of workers over 15 years old who have been trained (TyleLÐquadaotao): have a positive coefficient consistent with the author's initial expectations, with the Cronbach's Alpha of 1%, an increase of 1% in the proportion of people with a college degree increases the urbanization rate by 0.076%. The skilled labor force improve the competing capability of the economy, especially for workers operating in the non-agricultural sector, an important indicator to achieve the conditions to upgrade to urban status. Thus, skilled labor is an important factor to achieve economic growth, and economic growth creates favorable conditions for urban infrastructure adjustment, which helps increase the urbanization rate.

Provincial Competitiveness Index (LnPCI): PCI bearing a positive effect in line with the author's initial expectations and previous studies. With the Cronbach's Alpha of 1%, when the provincial competitiveness index increases by 1%, the urbanization rate will increase by 0.149%.. A high PCI may also indicate a higher standard of living, which may be a factor that attracts people to move to urban areas in search of better housing, education, and healthcare facilities.

Gross regional domestic product (GRDP): has a positive coefficient consistent with the group's initial marking expectations, with the Cronbach's Alpha of 1%, indicates that when the gross product in the area increases by 1%, it will make the urbanization rate increase by 2.73e-04%. This demonstrates that economic growth is an important factor in increasing the rate of urbanization in Vietnam. It also emphasized the importance of economic development in promoting urbanization in developing countries.

Population density of provinces in Vietnam (MDDS): with a positive sign in line with the initial expectation, with the Cronbach's Alpha of 1%, the model indicates that while other factors remain constant, when the population density increases by 1% then the urbanization rate increases to 0.02%. High population density is one of the main factors driving urbanization in Vietnam. Big cities, the center of the metropolitan area attract a lot of migrants from other parts of the country, leading to urban population growth and thereby helping to increase the urbanization rate.

City Number (SoTP): The regression model shows that $p\text{-value}=0.644>0.1$. From the model, it is not proven that the number of cities affects the urbanization rate in Vietnam. This is contrary to the original prediction of the author. Some of the reasons are that some cities do not have an increase in urbanization rate because the province/city does not have equivalent economic development. A weak economy often leads to no investment, no jobs, and low income, which can lead to hindering local urbanization.

Number of enterprises operated in each region in Vietnam in the period 2010-2021 (DNHD): Regression model shows that with the Cronbach's Alpha of 1%, when business activity increases by 1%, the urbanization rate will decrease by 6.22e-05%. This is contrary to the original hypothesis of the author. One of the reasons for the above results is because a higher degree of urbanization can lead to a higher cost of living, increased production costs, property taxes and higher labor costs. This leads businesses to move to neighboring suburbs to build factories, leading to a decrease in population, employment and goods and services in the city area and reduce the rate of urbanization in the city.

5. Discussion and conclusions

5.1. Policy implications

5.1.1. Increase service revenues

Identifying tourism as the strongest positive impact factor with the expectation of contributing significantly to the urbanization rate, and also a key economic sector of our country in the coming time, so we need to focus on developing tourism in a sustainable way,

developing tourism must be based on synchronous and community-based projects and plans, preserving traditional values but still promoting the strengths of "hidden beauty" of Vietnam's tourism.

5.1.2. Increase the proportion of trained workers over 15 years old

Based on the above regression results, the quality of labor positively affects the urbanization rate with the expectation of improving labor productivity to contribute to economic growth, we realize that focusing on training to improve the quality of human resources is very necessary.

5.1.3. Increase investment in Vietnamese provinces/ cities

The research model shows that investment has a positive influence on the urbanization rate in Vietnam. This finding contributes to supporting the pursuit of policies and measures to promote the progress of disbursement and attraction of investment, especially Foreign Direct Investment (FDI).

5.1.4. Improve the Provincial Competitiveness Index - PCI

The above research model shows that the PCI provincial competitiveness index has a positive influence on the urbanization rate in Vietnam. Improving the Provincial Competitiveness Index (PCI) in Viet Nam requires a holistic approach that addresses the various factors affecting competing capability.

5.1.5. Improve industrial production index

The above research model shows that industrial production index has a positive influence on the urbanization rate in Vietnam. This finding contributes to the pursuit of policies and measures to boost the index of industrial production in regions in Vietnam.

5.1.6. Increase population density

Population density is a variable that has a positive impact on the urbanization rate as analyzed above, so having solutions to continue maintaining the golden population structure period, thereby increasing job opportunities, diversification of professions in rural areas; improve the quality of vocational training and training according to labor market needs.

5.1.7. Increase in gross regional domestic product - GRDP

Based on the above regression results, the gross product in each province positively affects the urbanization rate with the expectation of increasing the income and living standards of residents in the region, we realize that focusing on economic development for each locality is very necessary and needs to be focused.

5.1.8. Improve the work of performed business

DNHD is currently a variable that has a negative impact on the rate of urbanization because in fact, although this variable increases in quantity, its quality is not guaranteed and has not been appropriately improved, so it becomes a negative impact factor. In order to overcome the situation of enterprises operating at a loss, which is a waste of resources, it is

necessary to take measures to reduce the number of "shell corporation" while improving the quality to help reduce losses and generate profits to the end of the year from both business and government intervention.

5.1.9. Policies of the Party and the State

In the coming time, it is necessary to continue to improve institutions and policies to facilitate the process of urbanization, construction, management and improve the quality of urban to meet the requirements of sustainable urban development construction and management. Focus on building and developing a sustainable and synchronous national urban system in terms of network. Promote housing development, synchronous, modern, linked and adaptable urban infrastructure system to climate change. Building and perfecting the urban government model; improve the effectiveness and efficiency of urban management and the quality of urban life, ensure social security and welfare, security, safety and urban order. Economic development of urban areas; innovate mechanisms, financial policies and investment in urban development.

5.2. Conclusion

This research article evaluates the impact of factors affecting the urbanization rate in Vietnam. The econometric model is built based on data collected from 63 provinces and cities of Vietnam with secondary data for the period 2010-2021. After running the model with 756 observations, the study has shown the influence of these factors on the urbanization rate of Vietnam.

The study has provided empirical evidence on the factors affecting the rate of urbanization in Vietnam, thereby contributing to affirming the pursuit of strategies and policies associated with the reality of the provinces in particular and Vietnam in general.

ECONOMIC INSTITUTIONS: A BARRIER OF REGIONAL COMPETITIVENESS OF THE RED RIVER DELTA REGION?

Dr. Nguyen Thi Phuong Thu

thunp@neu.edu.vn

Faculty of Development and Planning, National Economics University, Ha noi, Vietnam

Le Vu Thuy Tien

thuytienlevu02@gmail.com

Durham Univerity, London, United Kingdom

Abstract

The article studies a number of sets of criteria to measure regional competitiveness in the Red river delta region in Vietnam. The article chooses to use the EU's set of criteria to measure competitiveness of the Red river delta region, through groups of criteria (i) basic, (ii) efficiency and (iii) innovative and based on available statistics in Vietnam. The measurements of economic institution indicator will be focused on finding out whether it enhances or barrier the competitiveness of the Red river delta region. From that, draw some conclusions, policies implications and suggest orientations for further in-depth studies on the topic of regional competitiveness.

Keywords: *Economic institutions, Regional competitiveness, Regional competitiveness index, regional innovation, regional institutions.*

1. Introduction

Institutions can broadly defined as rules and norms for interacting in society. Institutions play a fundamental role in any country's economic growth and overall development performance. Institutions embody formal and informal rules devised by people that constrain or condition human activity and hence provide incentives that influence human behavior. Since institutions influence or even shape behavior, the extent to which they prompt or discourage growth-enhancing or other socially desirable activity is critical to whether a country achieves better economic or social outcomes. A strong relationship exists between the level of development and the quality of institutions that provide security, regulate economic activity, enforce the rule of law, and enable the public to take part in governmental decision making. Institutions encourage socially constructive behavior, help promote economic growth and other desirable outcomes. Institutions have close relationship with property rights enforcement and the rule of law and economic performance. Institutional quality is strongly related to the level of development. Data from the Worldwide Governance Indicators (WGI) project, which collects annual information on six dimensions of governance, reveal a strong relationship between the quality of governance over the long period and prosperity as measured by gross domestic product (GDP) per capita (Figure 1.1) (WorldBank, 2019).

Enhancing regional competitiveness is a common goal in regional economic policy making. Much of society's resources are allocated for this purpose, the region has been rediscovered as an important source of competitive advantage in a globalizing political economy (Scott, 1995; Cooke, 1997). In part, this rediscovery is based on studies of the success of highly dynamic regional economies and industrial districts which draw extensively upon local assets for their competitiveness. However, the rediscovery is also based on the insights of institutional economic theory, particularly its explanation of why territorial proximity matters for economic organization. Two conceptual strands stand out regarding that toward the regional competitiveness: (1) regional competitiveness is the sum total of enterprise-level competitiveness implemented in the region. or (2) simply reuse and redefine concepts from the macro level.

The Regional Competitiveness Index (RCI) has measured key elements of Competitiveness since 2010 for all NUTS-2 grant zones across the EU. With more than 70 comparable indicators, the index measures a region's ability to provide an attractive and sustainable environment for businesses and people to live and work in. The RCI provides a comprehensive and comparable picture of the competitiveness of all EU regions. The regional level described by the RCI allows the assessment of inequalities in competition between regions and monitoring of activity over time at the discrete spatial level. In most cases, the regional level is much more relevant than just looking at the country level. RCI should be seen as a tool to aid in the design of better policies and to monitor their effectiveness.

RCI scores facilitate the comparison of the competitiveness of one region with another. A dashboard designed for each region presents the region's scores and rankings, three indicator groups, and 11 pillars. The region's NLCT scores on each RCI component can then be compared with the mean scores of similar regions. The standard deviation of the similarity zone scores is considered as a measure of the change in scores within the group. If the scores of another region are one standard deviation less than the mean, the region is considered to have neither strengths nor weaknesses. If the region's score is one standard deviation more than the mean, it is considered to be performing well relative to the other regions, and vice versa.

Several authors have debated and suggested RCI (Gardiner, B., Martin, R. and Tyler, P., 2004, Huggins, 2011, Kitson, M., R. Martin and P. Tyler, 2004, Martin, R., 2005) for measuring the competitiveness of a region but the institution indicators given in the EU countries model are applicable in practices. The EU countries have proposed the structure of the RCI regional competitiveness index, which includes different aspects of competitiveness, divided into three groups: basic (including institutions, macroeconomic stability, basis infrastructure), efficiency (including higher education, labor market efficiency) and innovation (including technology readiness, state of business development and innovation). Competitive competence is a multidimensional concept, so research requires the coordinated efforts of many different subjects. The analysis of the RCI, three groups of 11-pillar indexes helps highlight the strengths and weaknesses of each region with the ability to assess the average level of each region with the average of the EU or other regions. The RCI is a single, comparable and transparent tool for national and regional planners responsible for regional development strategies, particularly in the context of coherent policy. These three groups of

indicators are detailed into 11 pillars as follows: i) BASIC INDICATORS: Institutions, Macroeconomic Stability, Infrastructure, Health, Basic Education; ii) EFFICIENCY INDICATORS: Further education and lifelong learning, Labor market efficiency, Market size; iii) INNOVATION INDICATORS: Technological readiness, Business maturity, Innovation.

2. Method

The proposal for the RCI starts from the premise that competitiveness cannot be measured directly because of its abstract, multidimensional essence, which means that it depends on many factors that cannot be determined conclusively, that are not independent and that do not have a known functional form. Nevertheless, it is reasonable to assume that competitiveness can be evaluated indirectly by analyzing a set of socioeconomic variables (indicators) which afford significant information about the multiple dimensions that make it up. Among the indicators, institutions indicator is a focal point. Suppose that for a given year t we have a number (m) of indicators for each of the n elements of our population. $I_i(k)$ denotes for the value reached by the element k in indicator i . For the construction of a synthetic indicator two order axioms established: (1) If two elements r and s present identical values in all the partial indicators ($I_i(r) = I_i(s); i = 1, \dots, m$), then their competitiveness must be equal; (2) If an element r presents, with respect to another element s , a greater or equal value in all partial indicators, and at least one of them is strictly greater, ($I_i(r) \geq I_i(s); i = 1, \dots, m$; with at least one j such that $I_j(r) > I_j(s)$), then the competitiveness of the element r must be greater than that of the elements.

This research was preceded by consistent and rigorous collection and analysis of data using intensive qualitative and quantitative research. The main data gathering tools for qualitative research were key informant in-depth interviews. The study used both purposive sampling and snowball sampling to collect data. This combination can be possible to provide the broadest range of information. The more information that can be obtained, the better the chance of a complete picture of the cases being studied. Selection of interviewees began with a purposive sample of individuals known to be expertise and practices in planning and/or to be in positions of particular influence within the local government. Sixteen interviewees from across different organizations/departments and government levels including central government, provincial government, three district-level governments, commune governments, donors and expert consultants were interviewed. Interviewees were either the Chief Executive Officer (CEO) (or equivalent), Mayors and elected members or department managers and senior service officers in the organizations. In this study, transcripts of interviews and direct experiences and documents (plans, decrees, guidelines, instructions, websites, journals, and other public documents produced and provided by the organizations involved) were analysed for exploring and discovering the indicators and factors influencing the competitiveness. These were managed and analysed by using computers, particularly software package Nvivo. The secondary data were collected from General Statistic Office, particularly from the Statistical Yearbook for quantitative analysis of the regional competitiveness in order to discover and measure the index.

3. Results

Based on these premises, the Regional Competitiveness Index of the Red river delta region measured by the distance methodology described. Figure 1 presents the results for all the ACs for the period 2017-2021. The values have showed that the institutions have been improved over the years.

Table 1. Regional Competitiveness Index of the Red river delta region

Indicators	Indexes	2021	2020	2019	2018	2017
BASIC INDICATORS	1.1. Time cost index of enterprises	7.81	7.93	7.07	6.65	6.66
	1.2. Informal cost index of enterprises	7.20	6.58	6.36	5.72	5.27
	1.3. Transparency Index	5.82	5.86	6.76	6.26	6.31
	1.4. Equality Business Environment among business sectors	6.56	6.72	6.20	5.17	4.72
	1.5. Cost entering market	6.79	7.66	7.54	7.40	7.65

3.1. Time cost index

Measure the time that businesses have to spend when carrying out administrative procedures, as well as how often and how long businesses have to suspend business for the state management agencies of the province to carry out the work. inspect.

Table 3. Time cost index of enterprises in the Red river delta region

Province	Sub-Index 4: Time Costs	Percentage of firms spending over 10 percent of their time on understanding and complying with regulations	Local government officials are friendly	Local government officials are effective	Firms don't have to travel many trips to obtain stamps and signatures	Paperwork is simple	Fees are listed publically	Time to do APs is shorter than regulations specified (%)
Bac Ninh	8.47	24%	82%	84%	78%	75%	95%	75%
Ha Nam	7.04	24%	81%	85%	76%	74%	91%	80%
Ha Noi	8.45	26%	75%	80%	72%	64%	94%	83%
Hai Duong	7.23	22%	83%	94%	79%	71%	99%	85%
Hai Phong	7.64	23%	73%	83%	69%	66%	90%	79%
Hung Yen	8.46	28%	79%	88%	74%	71%	95%	81%
Nam Dinh	8.14	14%	88%	90%	84%	81%	93%	84%
Ninh Binh	6.71	20%	83%	87%	84%	90%	91%	83%
Quang Ninh	8.52	21%	91%	88%	86%	87%	95%	87%
Thai Binh	6.79	27%	80%	83%	72%	76%	90%	79%
Vinh Phuc	8.46	14%	93%	94%	86%	87%	98%	89%

Source: VCCI (2021)

The cost and time that businesses have to spend to learn and implement the State's legal regulations in the provinces in the Red river delta region are generally quite similar. In which, the highest time cost that enterprises have to spend is in Hung Yen with 28% of respondents agreeing and the lowest in Vinh Phuc with 14% of respondents agreeing.

3.2. Informal Chargesindex - PCI

This index helps measure the level of informal costs that businesses have to pay as well as the obstacles these costs cause to the business activities of enterprises.

Table 4. Informal Chargesindex of enterprises in the Red river delta region

Province	Sub-Index 5: Informal Charges	Firms in my line of business usually have to pay for informal charges (%)	Percentage of firms saying that informal charges usually or always deliver expected results	Rent-seeking phenomenon is popular in handling administrative procedures for businesses (%)	Informal charges are at acceptable levels (%)	Percentage of firms paying informal payment to inspectors	Percentage of firms paying informal charges in business registration/ re-registration	Percentage of firms paying informal charges when implementing sublicense procedures	Percentage of firms paying informal charges to fire safety inspectors
Bac Ninh	7.27	37%	52%	59%	86%	19%	17%	57%	28%
Ha Nam	6.63	47%	60%	63%	87%	24%	15%	74%	42%
Ha Noi	7.15	38%	59%	56%	84%	23%	26%	67%	36%
Hai Duong	7.24	33%	51%	40%	86%	19%	16%	53%	30%
Hai Phong	6.70	44%	61%	59%	84%	28%	30%	64%	35%
Hung Yen	6.63	38%	72%	54%	83%	26%	16%	70%	50%
Nam Dinh	7.62	35%	51%	57%	91%	15%	22%	63%	23%
Ninh Binh	7.56	33%	90%	67%	96%	21%	22%	67%	30%
Quang Ninh	7.85	24%	42%	45%	90%	18%	30%	61%	12%
Thai Binh	6.46	55%	53%	65%	83%	31%	26%	73%	30%
Vinh Phuc	8.05	40%	51%	65%	95%	10%	21%	66%	50%

Source: VCCI (2021)

The average corruption index of the whole region is 50,276 (% of respondents agree), higher than the national average (48.73%). Thai Binh is the city with the highest corruption index in public agencies in the region with 55 (% of respondents agree). Quang Ninh is the city with the lowest corruption index in public agencies in the region with 24 (% of respondents agree)

3.3. Transparency Index - PCI

The Transparency Index is one of the most important indicators to distinguish which business environment is conducive to private sector development.

Table 5. Transparency Index in the Red river delta region

Province	Sub-Index 3: Transparency	Access to planning documents (1=Impossible 5=Easy)	Access to legal document (1=Impossible 5=Easy)	Transparency in bidding (% Yes)	Received information requested	Median days to receive information requested (Days)	Website information about provincial investment incentives is useful
Bac Ninh	6.39	2.65	3.00	85%	79%	5	30%
